As long as the discharge valve is closed the impeller is churning the water, and this energy is transformed into heat. If this operation is continued too long, steam might be generated. A small by-pass for liberating air relieves any possibility of steam pressure. Of course the proper thing to do is to open the discharge valve as soon as the motor is running at synchronous speed and allow the pump to begin discharging at its normal head.

There are numerous cases where centrifugal pumps driven by synchronous motors are used for suction dredging. As the pipe lines which carry the discharge are extended from point to point as the dredge continues its work, a large change in the friction head occurs which necessitates two-speed drive for the pump. This requirement can be met by using a two-speed helical gear.* The over-all maximum efficiency of a centrifugal pump directly driven by a 300-hp. synchronous motor is shown in the chart on page 604.

Each installation of centrifugal pumps is a special problem, and both motor and pump must be designed as such if best results are to be secured. Generally speaking, centrifugal pumps are designed to operate at constant speed. Synchronous motors with speeds as low as 72 r.p.m. are used directly coupled to low-head pumps. High-head pumps with speeds as high as 1200 r.p.m., or even 1800 r.p.m., are also directly coupled.

Unity Power Factor Operation.—A synchronous motor designed for so-called unity power factor operation has a fixed exciting current which cannot be exceeded, so that absolutely unity power factor cannot be maintained if the load fluctuates. As the load drops off the power factor will change to leading, but the change in power factor from full load to quarter load is surprisingly small. From one-and-a-quarter load to one-half load the change in power factor is less than 10 per cent. At one-half load the power factor is slightly leading and at one-and-a-quarter load slightly lagging. If the load should be removed entirely from the motor, it would operate at approximately zero power factor up to about one-half of its rated kva. capacity.

*In one plant using this drive which the writer inspected the energy cost was only five-sixths of the amount that fuel cost when steam was used for the same purpose. Furthermore, the motor-driven suction dredge was handling considerably more material. If the present price of coal was taken into consideration, the energy cost would be only about five-twelfths of the full expense.

The friction losses in the motor would constitute a load, so that in practice the power factor could never reach zero.) The limitation to the exciting current prevents the motor from carrying its full kva. rating. Of course, variations of design will change the characteristics of motors, so the preceding statements are only general and must be modified under certain conditions. The extent to which a power user can afford to go in installing synchronous machines depends largely on the annual cost of power. The advantage to be obtained may run anywhere from 10 per cent to 30 per cent of this amount.

Correcting Power Factor.—In the case of an isolated plant generating its own alternating current, the use of an over-excited synchronous motor at a leading power factor is often very desirable. Such a motor if properly designed may operate at a power factor, say, 80 per cent leading, while at the same time carrying three-quarters of its rated mechanical load in horsepower.

Under this condition the motor may exert nearly the maximum corrective effect on the system's power factor. The magnitude of the system load and the power factor must be taken into consideration, however.

This problem of power-factor improvement cannot be met in the future, as it has been in the past, simply by the central station installing large synchronous condensers. It will become more and more desirable to have a connected load of many fair-sized synchronous motors scattered over the system. This is much better from the standpoint of voltage regulation, transmission efficiency, etc., than the old method of combining all the power-factor correction for the circuit in one or more synchronous condensers.

The result will be that central stations will encourage the use of synchronous motors more and more on their lines. This tendency is already apparent in many sections of the country, especially where large individual users of power are scattered over the system.

Changing Aspects of Factory Lighting Legislation

More Elaborate Classification of Requirements Desirable—Glare More Important than Intensity—Emergency Lighting Receives More Attention—Portable Photometer Facilitates Enforcing Legislation

BY C. E. CLEWELL

Assistant Professor of Electrical Engineering, University of Pennsylvania

This article and one to appear subsequently have been written to review the marked changes which have taken place in state factory lighting legislation during the past months and to outline the principal revisions in the Factory Lighting Code of the Illuminating Engineering Society since June 1, 1917. Emphasis is placed upon the five main elements which call for legislation in this field and also upon the chief points which have come up for discussion in designing new codes and in revising the codes which have been in force since 1915. Notes are included on recent instances which have an important bearing on the intelligent enforcement of such regulations. Plans to give lectures on factory lighting to the state factory inspectors of Pennsylvania and New Jersey at the University of Pennsylvania are also outlined.

A REVIEW of the original I. E. S. Code of Lighting¹ for factories, mills and other working places seems especially desirable at this time for several reasons: (1) Because important revisions were made by the committee on lighting legislation of the Illuminating Engineering Society in June, 1917; (2) because a complete revision of the Wisconsin code has been under way since the fall of 1917; (3) because a lighting code committee was appointed in 1917 by the Ohio Industrial Commission to prepare a set of factory lighting regulations² for that State, and (4) because of an important revision of the codes which were adopted in 1916 by the States of Pennsylvania and New Jersey as made in January, 1918.

¹The original Code of Lighting for factories, mills and other workplaces, as discussed from various standpoints by the writer during the past two years (see ELECTRICAL WORLD, Vol. 66, No. 21, p. 1135, and Vol. 69, No. 25, p. 1203; *Factory* for September, 1917; *Industrial Management*, Vol. LV, No. 2, p. 117) contained regulations on the following principal points: (a) Intensity required for various classes of work, (b) distribution of light, (c) inspection and regular maintenance, (d) location of switches at entrances, (e) lighting of stairs and passages, (f) advantage of the overhead system of lighting, and (g) auxiliary or emergency lighting.

²A draft of this code is now available.

To the four points cited there may be added the significant appointment by the committee on labor of the advisory commission, Council of National Defense, of a committee on lighting³ for preparing a code of lighting for mills and workshops, having in mind four points, (a) the conservation of the eyesight of employees, (b) safety, (c) increased labor efficiency, and (d) larger output and decrease in spoilage.

From this list of very recent developments it will appear that the last half year has witnessed an unusual interest in the question of lighting rules for factory plants. Moreover, the two years which intervened between the preparation of the I. E. S. code in 1915 and the present have afforded additional experience and data on which to base the revisions of June, 1917. A number of interesting technical points have arisen in this work of revision, making the present an appropriate time for a brief discussion of these developments.

REVISIONS OF THE I. E. S. CODE

The original code of the Illuminating Engineering Society contained regulations on seven principal points as outlined in a preceding paragraph, these seven points being included in nine articles suggested as a basis for legislation or guidance. Following the issuance of this code in 1915, the States of Pennsylvania and New Jersey adopted it in slightly revised form, and it became effective in both States in 1916. After about two years these two States asked for revisions of the original code, if any were desirable, and requests for co operation were received by the committee on lighting legislation from Wisconsin and Ohio, all of which convinced the I. E. S. committee that the time had arrived for a

³ELECTRICAL WORLD, Jan. 5, 1918, on "Activities of the Engineering Societies in War Work."

careful study of its original code before further adaptations were made.

As a result the whole matter was carefully considered at a meeting in New York in June, 1917, and a decision reached to limit the suggested regulations to basic points, as follows: (1) Intensity requirements (which include the question of classifying industrial work), (2) the elimination of glare by proper shading

take into account those cases of rough manufacturing which involve a closer discrimination of detail than is implied by rough machinery or rough assembling. This new class is given under heading (e). Several minor, although important, changes are made in the intensity requirements.

Thus, for rough manufacturing the original code called for a minimum intensity of 1.25 and gave a range of 1.25 to 2.5 foot-candles for desirable practice. The revised rules do not change the minimum but increase the range from 1.25-2.5 to 2.0-4.0 foot-candles. The minimum intensity is given second place in the revised code so as to place extra weight upon the higher values of ordinary practice. Figs. 1 and 2 show these changes and values graphically, the former giving a comparison between the more important older values and the new revised values, while Fig. 2 shows the new values in complete form.

The note at the end of Rule 2 calls for measurements by a portable photometer. At the end of the last paragraph of Article V of the old code the use of such an instrument is recommended. The committee included a definite statement in the revised rules regarding the use of such an instrument with greatly increased confidence due to the commercial perfecting of the foot-candle meter (Figs. 3 and 4), which now places at the disposal of the state inspectors an inexpensive and sufficiently accurate instrument for checking up intensity values. Representatives of state labor boards have expressed the opinion that the appearance of such an instrument removes the chief difficulty in the enforcement of such legislation.

GLARE MORE IMPORTANT THAN INTENSITY

Rule 3 of the revised code introduces into the body of the code the item of glare, which is looked upon as an item of even greater importance, in the present condition of industrial lighting, than the intensity require-

of lamps, (3) the distribution of light on the work, (4) emergency lighting, and (5) pilot or night lamp control near entrances. A comparison of these revised rules with the original code can readily be made from the parallel passages in Table I, and also Tables II and III, which serve as a basis for the discussion to follow.

DISTINCTION BETWEEN VALUE OF DAYLIGHT AND ARTIFICIAL LIGHT

Referring to Tables I, II and III, it will be seen that the revised rules omit all efforts to include daylight, except indirectly in the last two lines of Rule 1. This reference to natural light implies indirectly that the intensities of daylight which correspond with those for artificial light given in Rule 2 are satisfactory, namely, that there is no difference between the minimum requirements of artificial and of natural illumination. In the second paragraph of Article I of the original code the minimum requirements for natural lighting were set at three times those for artificial lighting. While experience indicates that some distinction between the two kinds of light, as outlined in the original code, is warranted, the committee did not feel able, in the present state of the art, to assign any definite figure for this difference, in spite of the fact that in 1915 such a distinction seemed advisable in definite form.

A comparison of Article V with Rule 2 shows that a slightly more elaborate classification of work seems desirable. Thus roadways and yard thoroughfares and office work are two new classes. Further, it was felt advisable to separate storage spaces and stairways, which were combined in the original code, making them into separate heads and increasing the range of intensities for ordinary practice for stairways. The committee also felt it desirable to insert a new classification between rough and fine manufacturing work to

FIG. 1—COMPARISON OF THE INTENSITIES REQUIRED BY THE 1915 I. E. S. CODE OF FACTORY LIGHTING WITH THE REVISED INTENSITIES RECOMMENDED BY THE 1917 I. E. S. COMMITTEE ON LIGHTING LEGISLATION

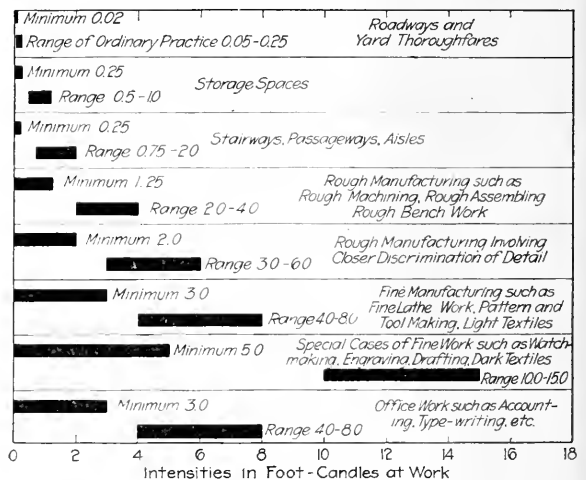

FIG. 2—MINIMUM INTENSITIES AND RANGE RECOMMENDED FOR ALL CLASSES OF WORK LISTED IN THE REVISED I. E. S. CODE

ment. Considerable discussion has arisen during the past months as to the possibility of drafting a regulation covering glare which will be definitely enforceable. Obviously, such a rule, if readily interpreted, would be preferable to the general statement of Rule 3. It has been found difficult to formulate such a rule in definite terms, although there is reason to believe that a more tangible wording will develop in the near future. This

atter will be discussed in more detail later in connection with the recent revisions of the Wisconsin code.

Article VI and Rule 4 are comparable. Here again, with Rule 3, there has been considerable agitation for a definite statement of what is meant quantitatively by "a good distribution"; in other words, what ratio of maximum to minimum intensity could be considered as falling within the meaning of a *good* distribution.

TABLE I—PARALLEL PASSAGES FROM THE ORIGINAL AND THE REVISED I. E. S. CODE OF LIGHTING FOR FACTORIES, MILLS AND OTHER WORKPLACES

ORIGINAL CODE, 1915

ARTICLE III. All buildings, whether old or hereafter constructed, must be provided during those hours of work when natural light is insufficient or not available with adequate artificial light according to the following articles.

ARTICLE V. ARTIFICIAL LIGHT; INTENSITY REQUIRED. The average illumination intensity throughout any month actually measurable in foot-candles on a horizontal plane through the work is to conform to the following table. Uncertain cases which arise as to how to classify given manufacturing operations are left to the judgment of a lighting expert.

Class of Work	Minimum Foot-Candle Intensity	Desirable Foot-Candle Intensity
Passage, passageways, stairways and the like	0.25	0.25-0.5
Light manufacturing and other operations	1.25	1.25-2.5
Heavy manufacturing and other operations	3.50	3.50-6.0
Special cases of fine work		10.00-15.0

Where operations are performed on the sides of the work in which they shall be classified according to this table, and if the illumination is furnished from an overhead system, it shall preferably be not less than 50 per cent of the foregoing values, when assured on a vertical surface. If the illumination is furnished by an individual lamp or lamps close to the work, the intensity shall conform to the minimum or desirable intensities required in the foregoing table.

NOTE.—As a guide to inspectors and others it may be stated that with modern lamps roughly 1 cp. per square foot produces effective illumination of 3 foot-candles when the lamps are arranged according to the uniformly distributed overhead system, with mounting heights ranging from 12 ft. to 16 ft. above floor, and when the light is directed from said lamps to the work in an efficient manner. A rough idea may thus be secured of the candle-power per square foot necessary to conform to the foregoing table of intensities by taking one-third of the intensities given in the foregoing table.)

Thus for fine manufacturing and other operations the minimum foot-candle intensity is 3.5, which is approximately equal to 1.2 per square foot. The use of a portable photometer or illuminometer, however, is recommended for the determination of existing intensities, and all uncertain cases are finally to be established by these instruments.

ARTICLE VI. LAMPS AND MACHINERY, jointly, are to be arranged as to avoid the casting of shadows over belts and other obstructions on important parts of the work, and the distribution of light from the lamps should be such as to avoid sharp contrasts of light and shade on the work.

ARTICLE XI. AUXILIARY LIGHTING should be provided for all large work spaces, such lamps to be in operation simultaneously with the regular lighting system, so as to be available in case the latter should become temporarily deranged.

ion. This subject also will be referred to in greater detail under the Wisconsin revisions which are to be stated later.

There has perhaps been no rule which has received more careful attention than Rule 5, concerning emergency lighting. It has been felt that too drastic a rule on an auxiliary system might work a hardship in some cases, whereas there can be little doubt as to the wisdom of such a provision for the great majority of industries. It is believed that Rule 5, in its revised form, covers the practical needs better than was the case with the old Article XI. The wording of Rule 5, however, leaves the interpretation of ways and means for the supply service for the emergency lamps to the judgment of the industrial commission or to its engineering representatives.

Old Article VIII contains a reference to control apparatus at the entrances of certain spaces. New Rule 6 makes such switching or controlling apparatus, at least pilot or night lamps, essential for all main points of entrance.

SUMMARIZATION OF CHANGES WHICH HAVE BEEN MADE IN I. E. S. CODE

In summarizing the changes which have been made in the original I. E. S. code, a fair conclusion of the work of the committee on lighting legislation can be secured from the accompanying tables. Clauses or articles which were felt to be superfluous in the original draft have been omitted, and other important

AS REVISED, 1917

RULE 1. GENERAL REQUIREMENT: Working or traversed spaces in buildings or grounds shall be supplied during the time of use with artificial light in accordance with the following rules, when natural light is less than the intensities specified in Rule 2.

RULE 2. INTENSITY REQUIRED: The desirable illumination to be provided and the minimum to be maintained are given in the following table:

	Foot-Candles* at the Work		
	Ordinary Practice	Minimum	
(a) Roadways and yard thoroughfares....	0.05-0.25	0.02	
(b) Storage spaces	0.50-1.00	0.25	
(c) Stairways, passageways, aisles	0.75-2.00	0.25	
(d) Rough manufacturing such as rough machining, rough assembling, rough bench work	2.00-4.00	1.25	
(e) Rough manufacturing involving closer discrimination of detail	3.00-6.00	2.00	
(f) Fine manufacturing such as fine lathe work, pattern and tool making, light-colored textiles	4.00-8.00	3.00	
(g) Special cases of fine work, such as watchmaking, engraving, drafting, dark-colored textiles	10.00-15.00	5.00	
(h) Office work such as accounting, typewriting, etc.	4.00-8.00	3.00	

*The foot-candle, the common unit of illumination, is the lighting effect produced upon an object by a standard candle at a distance of one foot; at two feet the effect would be not one-half foot-candle, but one-fourth foot-candle, etc. A lamp which would give off 16 cp. uniformly in all directions would produce a uniform illumination of one foot-candle at a distance of four feet in any direction.

NOTE.—Measurements of illumination are to be made at the work with a properly standardized portable photometer.

RULE 4. DISTRIBUTION OF LIGHT ON THE WORK: Lamps shall be so installed in regard to height, spacing, reflectors or other accessories as to secure a good distribution of light on the work, avoiding objectionable shadows and sharp contrasts of intensity.

RULE 5. EMERGENCY LIGHTING: Emergency lamps shall be provided in all work-space aisles, stairways, passageways and exits to provide for reliable operation when, through accident or other cause, the regular lighting is extinguished. Such lamps shall be in operation concurrently with the regular lighting and independent thereof.

features have either been revised or added after the most careful and painstaking study by experts in this

FIG. 3—THE FOOT-CANDLE METER, WHICH PROMISES TO BE OF MUCH HELP IN THE CONTROL OF INDUSTRIAL LIGHTING

field. New and important additional weight will be given to these changes by the discussion in a subsequent article of the points which have come up through

the work of committees or engineers in various states where attention has been directed to lighting legislation during the past six or eight months.

FIG. 4—READINGS OF ILLUMINATION MAY BE MADE VERY SIMPLY WITH FOOT-CANDLE METER

Two fundamental requirements must be met if state regulations of this kind are to be enforced intelligently. The one is to place at the disposal of the state factory inspectors instruments suitable for measuring illumination intensity, and the other is to train the inspectors

TABLE II—ARTICLES OF 1915 I. E. S. CODE WHICH WERE OMITTED OR RADICALLY REVISED IN 1917 CODE

ARTICLE I. DAYLIGHT.—All buildings hereafter constructed must be provided with adequate window area. Awnings, window shades, diffusive or refractive glasses must be used for the purpose of improving daylight conditions or for the avoidance of excessive brilliancy wherever they are essential to these ends.

The windows, skylights, saw-tooth or other roof lighting constructions are to be arranged with reasonably uniform bays, and the daylight openings shall be so designed and proportioned that at the darkest part of any work space, when normal exterior daylight conditions obtain, there shall be available at least a minimum intensity equal to three times the minimum intensities given in Article V. for artificial light.

NOTE.—The intensity requirements for daylight are higher than those for artificial light because the physical condition of the eye during the daytime is usually such as to require a higher intensity of natural light for satisfactory vision than is required at night under ordinary well-designed artificial lighting systems.

ARTICLE II. Old buildings at present constructed and not having adequate window area must be provided with adequate artificial light according to the following articles, so as to supplement the natural light during normal daylight hours.

ARTICLE IV. Adequate intensity of the light must be provided for each class of work, both on a horizontal plane as well as on a vertical plane passing through the work, according to Article V. In all cases, however, glare on working surfaces is to be avoided as it tends to reduce the visual efficiency of the workmen and to increase the likelihood of accidents.

ARTICLE VII. INSPECTION AND REGULAR MAINTENANCE of all lighting systems is required in spaces where work is being conducted, and in no case must the lighting devices, whether windows, lamps or auxiliaries such as globes and reflectors, be allowed to deteriorate, due either to dirt accumulations or to burned-out lamps, more than 20 per cent below the minimum intensity values required by Article V.

ARTICLE VIII. ROADWAYS, YARDS AND PLACES NOT USUALLY FREQUENTED must either be provided with illumination during working hours when natural light is absent or partly absent, to make them safe against accident to employees traversing or engaged in such places, or a convenient control or controls must be placed at the entrance to basements, stock rooms and the like, so that a person on entering can readily turn on the lamps beforehand.

ARTICLE IX. STAIRWAYS AND PASSAGEWAYS must be provided with lamps and reflectors or shades carefully located so as to shed their light generally over the entire space or spaces involved, and in sufficient quantity to make the stairways and passages safe against accident to employees traversing or engaged in such places. For intensities see Article V.

ARTICLE X. Each working space is preferably to be illuminated by lamps mounted overhead according to the system of general lighting, in preference to individual lighting. The overhead method of lighting, besides possessing many other advantages, also tends to reduce dark spots throughout the floor area, a feature usually objectionable with the use of individual lamps. This particular article is not an absolute requirement, but a suggestion enforceable at the discretion of a lighting expert.

themselves in the fundamentals of illumination so that they may be capable of sizing up a lighting installation for its main defects at a glance, and at the same time may appreciate the economic advantages of good factory lighting to such an extent that the enforcement of such rules will appeal to them and that they, in turn, may convincingly represent to the factory owner that

TABLE III—NEW RULES WHICH WERE INSERTED IN 1917 REVISION OF I. E. S. CODE THAT HAVE NO PARALLELS IN 1915 CODE

RULE 3. SHADING OF LAMPS:

Lamps shall be suitably shaded to minimize glare.

NOTE.—Glare, either from lamps or from unduly bright reflecting surfaces, produces eye-strain and increases accident hazard.

RULE 6. SWITCHING AND CONTROLLING APPARATUS

Switching or controlling apparatus shall be so placed that at least pilot or night lights may be turned on at the main point of entrance.

the adherence to such rules is in no sense a hardship but a benefit to his employees and consequently to his plant as a whole. One channel through which education of this kind is planned for the definite help of the inspectors in two states, along with details of the new and forthcoming state codes which have grown out of the revisions of the I. E. S. code discussed in this article, will be outlined in the subsequent paper on the same general topic.

Fan, Blower and Air-Compressor Applications

With reference to his contribution on "Fan, Blower and Air-Compressor Applications," which appeared in the *ELECTRICAL WORLD* for Jan. 26, Prof. C. E. Clewley writes:

"My attention has been directed to a possible misinterpretation which may be made of the statement on page 197 reading: 'With an alternating-current supply all types may be driven by induction motors.' C. M. Lynge of the Pittsfield Works, General Electric Company, has indicated to me that, while this statement is literally true, it might have been elaborated to include both single-phase and three-phase supply.

"Mr. Lynge is engaged in the design of alternating current motors for propeller fans, and he mentions the development by the General Electric Company of a straight repulsion-type motor known as the type H motor for operating propeller fans, and also the fact that exhaust fans are operated most satisfactorily by motors possessing series characteristics in order to give positive starting and to compensate for load changes due to restricted inlets or outlets, to opposing winds and the like. On this account the straight repulsion motor, as pointed out by Mr. Lynge, is desirable. A motor possessing series characteristics may, in fact, readily be used since the direct-current propeller fan is always under load irrespective of outlet restrictions and cannot therefore reach excessive no-load speeds.

"Mr. Lynge also points out the fact that when an induction motor operates a fan in a duct system against a restricted outlet the motor will be heavily overloaded because of the corresponding drop in speed, and that the repulsion motor is therefore preferable to the induction type for fan service. These comments by Mr. Lynge are submitted for the purpose of avoiding any misunderstanding of the statement referred to above."

Logic of Public Utility Consolidations

Both Physical and Fiscal Combinations Are Economical of Investment and Operating Cost and a Public Benefit—Statistics of Progress
—Centralized Power Production

BY CLARENCE P. FOWLER

IT IS generally conceded that public service enterprises are natural monopolies and that the best interests of the public are served when such undertakings are operated as monopolistic but regulated enterprises. When such monopolies are properly regulated and at the same time protected from the unjust attacks of the ever-present demagogue the necessity for competition vanishes. Competition as a means of checking certain corporate abuses has proved itself damaging to the investor in public service securities and it has also been demonstrated that a competitive situation in the operation of utilities is a menace to public welfare.

The inherent monopolistic nature of the public service business is accorded the fullest recognition in those states where commission supervision of public service corporations is most firmly established, notably in New York, New Jersey, Massachusetts and Wisconsin. The position taken by the Massachusetts and Wisconsin commissions is reflected in recent decisions pointing out the failure of competition as a regulator of public utility service and rates.

COMPETITION AND REGULATION ARE CONTRADICTORY

The suppression of competition in furnishing public services has been the outgrowth of bitter experience. In fact, competition and commission regulation are contradictory, and the latter to be effective should be of such a nature that the profits from any one enterprise should not be sufficiently large to warrant wasteful duplication of capitalization through competition for the same business. Particularly is this true when, as is most frequently the case, such competition affords no additional facilities or service and is neither an extension or improvement over existing service.

The unified method of handling public service enterprises is co-operation whereby waste, duplication and the depleting warfare of competition can be avoided. It may also be termed the labor-saving, capital-conserving and modernizing appliance of the public service business.

The tendency to unite groups of public service properties, whether contiguous or not, suggests that consolidations may be divided broadly into two radically distinct classes—physical and fiscal.

The actual union of service in contiguous properties generally involves a certain amount of physical reorganization, bringing the system into unified action and securing the full advantage of single equipment and management. Practically without exception, the public gains by every consolidation of this character.

The American steam railroad corporation may be said to be the pioneer in the movement toward physical consolidation in the public service business on this continent. As an illustration of the adverse circumstances which confronted the shipper or traveler on the early American railroad the conditions at one time existing between New York and Chicago are typical.

One part of this route, between Albany and Buffalo, a distance of only 297 miles, was originally served by no less than eleven individual railroads, owned by as many distinct companies.

Then, again, to those engaged in commerce and transportation it became evident that, with the growth in population, the exchange of commodities between districts of production and consumption would be seriously hampered by unrestrained competition between rival lines, the effect of which is to favor certain towns and cities known as competitive points which are served by two or more railroads. At competitive points, without consolidation of the properties interested, freight rates are usually fixed at little above the cost of transportation, making it necessary for the non-competitive points served by only one line to provide the major portion of the funds required for operating charges, interest and dividends. As a result of this state of affairs population and industry become congested at localities where rail and water competition reduces the cost of transportation, thus rendering it extremely difficult for many industries to succeed in locations which are served by no more than one line of railroad. If, however, a consolidation of railroads, serving a certain territory, is effected, it is conceivable that with such a readjustment of rates between competitive and non-competitive points each will contribute its proper share to the operating expenses and fixed charges of the various constituent companies.

GREAT RAILROADS COMPLETELY UNIFIED

The most recent and impressive example of the consolidation of public service corporations and the fullest recognition of its advantages is found in the decision of our federal government to unify the operation of all of our great transportation arteries into one gigantic railroad system. This contemplates the pooling of all traffic and facilities, the common use of terminals, tracks and equipment, and the hauling of freight by the shortest route regardless of billing.

While this is not a time for captious criticism, however, it is worthy of note that the government has for a generation denounced pooling and has, through the Interstate Commerce Commission, succeeded in repressing it. The adoption of pooling now justifies the assumption that its suppression in the past may be regarded as an error, for the reason that if this method of operation offers the nation a more effective conduct of the industries incidental to the war, it seems reasonable to affirm that it would in the last thirty years have increased the effectiveness of the industries of peace.

Fiscal consolidations, of which the holding company is an example, possess the advantage of bringing a group of properties under a single and intelligent management with strong financial backing and render it possible to make economies and give better service which benefits the public. The holding company greatly

increases the development and service efficiency, as the different departments of operating companies included in a holding company are constantly under the stimulus of competition with similar departments in other companies of the group.

Holding companies make possible the procurement of capital for the development of public utilities which would otherwise not be developed at all or at best would be incompletely or inefficiently expanded. In rare instances are communities able to supply adequate funds for the creation and development of public services of the most approved type. The necessary capital must be secured from without, and this is especially advantageous for sections not fully developed, which are thus enabled to draw upon older and richer portions of the country. The capitalist, as a rule, is not willing to scatter investments in small isolated units throughout the country because it is practically impossible to give each one the proper attention. He prefers rather to invest in the holding company, relieving himself of the burden of supervision while, at the same time, securing a desirable diversification of risk. Moreover, the financial strength and prestige of the holding company is able to command capital and purchase materials and supplies on more favorable terms than the small individual company, and this means better rates.

It is of interest to show the tendency toward the holding company idea in the electric central-station industry as reflected by recent statistics compiled from authentic sources. These figures were gathered primarily to show the number of central stations owned or controlled by syndicate interests, the number owned independently and finally the number of municipally owned plants. These investigations were confined to towns and cities of 1000 population and more and are subdivided separately for communities of from 1000 to 5000 population, from 5000 to 10,000 population, 10,000 to 50,000 population and of more than 100,000 population. The totals for the entire country, eliminating, of course, communities under 1000 population, show that out of 4774 electric lighting plants 29 per cent have syndicate affiliations, 48 per cent are independent and 23 per cent are municipally owned.

It appears that the largest proportion of syndicate plants is in the Eastern States, with the next largest in the New England States, the Western States being third, Middle States fourth and Southern States last. The percentage of municipal plants is largest in the Middle States, with the South next and West third.

PROPORTION OF SYNDICATE PLANTS GROWS

The proportion of syndicate plants becomes larger as the size of the communities increases. Thus the proportion of syndicate plants advances from 20 per cent of the total number of plants for the smallest towns to 87 per cent in cities of the largest size. Conversely, the proportion of independent plants decreases as the size of the community increases; where it was 55 per cent of the total in towns of 1000 to 5000 inhabitants, it decreased to 10 per cent in cities of the largest size. The proportion of municipal properties also decreases as the size of the community increases. Where municipal plants formed as much as 25 per cent of the total for towns of 1000 to 5000 population, the proportion decreased to 3 per cent for the largest cities.

Of approximately \$5,000,000,000 securities invested

in street railways, about 82 per cent are organized into or affiliated with holding companies. Of about \$3,000,000,000 securities outstanding in the electric light and power business, about 83 per cent are operating subsidiaries of holding companies. Of the \$1,500,000,000 outstanding securities of gas companies, in excess of 66 per cent are organized into or affiliated with holding companies. Thus out of approximately \$9,500,000,000 traction, electric light and gas capital about 80 per cent is now organized into or affiliated with holding companies.

ADVANTAGE OF CENTRAL ELECTRICAL PLANTS

Centralized electric power production, with a single high-tension transmission network serving a large area, forms a typical example of public utility consolidation, which is justly claiming additional attention.

Interesting figures concerning an electric lighting and power system serving one of our largest metropolitan centers may be cited. The average yearly load factor (or the ratio of the average to the maximum load) was only about 30 per cent. Further, 97 per cent of the total kilowatt-hour output was produced by 50 per cent of the generating capacity, while it was necessary to have an investment in the remaining 50 per cent of the generating capacity to handle peak loads; but this latter half of the generating capacity generated but 3 per cent of the output. In other words, it may be stated that 50 per cent of the generating equipment was operated at about 46 per cent load factor, whereas the balance of the generating apparatus was operated at only about 5 per cent load factor. This example of the rather poor earning capacity of a large portion of the investment points to the urgent necessity for the creation and development of unified power systems.

That consolidated systems of power supply have not reached their fullest development is illustrated by the writer's recent experiences in the investigation of already extensive properties of this type, which contemplate further transmission line connection with similar systems serving contiguous territory but controlled by outside financial interests.

Modern hydroelectric systems operate to prevent the monopolistic use of water powers, so common in past years, and make possible the subdivision and distribution of these powers in the smallest units, thereby rendering the greatest good to the greatest number. In fact, not only do these hydroelectric enterprises make possible the supply of water power to a great many small consumers that could not be supplied without them, but through the medium of long-distance electrical transmission several powers on the same stream, or even different streams, may be linked together physically, and with the power of several watercourses so connected under common control a great diversity in power demand and supply is secured. Diversity in power supply often means that it is practicable to match the minimum discharge on one stream with a higher on another or to interchange power of streams having large storage capacity with those having little or none, which increases reliability of power supply and in many cases avoids the use of expensive auxiliary steam power, resulting in advantage to the public in keeping down rates and with common control giving the consumer at one point the advantage of securing water power from another point, perhaps 200 miles (321.8 km.) away.

Increasing Carrying Capacity of Underground Cable

The Substitution of Crude Vaseline for Air in Ducts Will Reduce Heating Effect, Eliminate Hot Spots, Decrease Electrolysis and Afford Mechanical Protection

BY E. O. SCHWEITZER

Chief Testing Engineer Commonwealth Edison Company

REALIZING that the dissipation of heat from cables is limited by the high heat resistance of the cables and surrounding medium, the writer has conducted a laboratory investigation in which the space between a section of cable and the inclosing duct was filled with crude vaseline. As a result of the test it was concluded that such practice increases the carrying capacity considerably, eliminates hot spots, decreases electrolysis and affords mechanical protection. Before the practical value of such an arrangement can be determined, however, it will be necessary to conduct investigations in connection with actual installations.

The tests were made on a 45-ft. (13.7-m.) length of 250,000-circ. mil., 12,000-volt, three-conductor cable, 15 ft. (4.6 m.) being run through stone conduit. Measurements of the copper and sheath temperatures were made at different points within the conduit by means of thermocouples. The joints and ends of the conduit were sealed with concrete, a pipe being introduced at either end for filling purposes. The three conductors were connected

in series and current was circulated through them at low pressure. No pressure was applied between conductors and sheath during the various heat runs. A general view of the set-up is shown in Fig. 1.

COOLING MEDIUM EMPLOYED

Crude vaseline, commonly known by the company's employees as "cable grease" and called "dark petroleum" by the manufacturers, was used in this test, as it was found to be inexpensive and to possess good characteristics as a filler for the space between the duct and cable. It has a very high viscosity and does not become fluid at any safe operating temperature for cable. These properties tend to prevent its escape through concrete or tile ducts and may be considered real advantages should the ducts prove pervious to highly

fluid materials. However, it is generally held that concrete is quite impervious, as the latest engineering experience and data indicate that it is being successfully used in tanks for the storage of oil. The filling of the ducts presents no serious difficulty as the grease can be heated until fluid and readily pumped in.

Other methods for the removal of heat from cable in duct lines have been tried, but all of them appear much inferior to the crude-vaseline plan. The use of air blowers by the Duquesne Light Company, Pittsburgh, Pa., for cooling an overheated duct line lowered the temperature of the cable by about 12 per cent. The

high-capacity blowers necessary in alternate manholes make the cost of such a cooling method prohibitive and applicable only in isolated cases. Dissipation of heat by circulating water, tried by other companies, is also inferior on account of the danger from cable failures due to defective sheaths, electrolysis and corrosion.

Some preliminary experiments on improving the heat-dissipating quality of the crude vaseline by introducing other

materials, such as graphite, seem to show that the additional cost will offset any advantage. This phase of the subject will probably be investigated further, however. At the same time the favorable effect of introducing flake graphite in the cement itself will be determined. The possibilities of both these lines of development are strictly limited, however, by the characteristics of the cable now in use.

The "internal" heat resistance of the conductor and belt insulations of cables now in service is a fixed and unalterable quantity. On the other hand, the "external" heat resistance from the cable sheath to the earth surrounding the ducts is a variable and can be decreased considerably by replacing the air now present by materials having better heat conductivity, such as crude vaseline. The resulting improvement in heat dissipa-

FIG. 1—VIEW OF LABORATORY IN WHICH CARRYING CAPACITY OF CABLE WAS TESTED

tion from conductor to earth, however, will depend on the relation of the "internal" to the "external" heat resistance. This relation for any fixed cable installation is a definite ratio which increases with any reduction in the "external" heat resistance. The degree of effectiveness of any cooling means is thus limited, depending upon the value of this temperature gradient in the cable itself.

For cables now in service test results showed this "internal" heat resistance to be about 60 per cent of the total, with air in the ducts. Hence, if it were possible to introduce a perfect conductor between sheath and earth, the current-carrying capacity could be in-

FIG. 2—EFFECT OF CRUDE VASELINE FILLER ON CARRYING CAPACITY OF CABLE

creased only 29 per cent. But if the "internal" resistance were 50 per cent under such ideal conditions, the current-carrying capacity could be increased by 42 per cent. Therefore it is evident that the greatest obstruction to rapid dissipation of heat from cables now in use is in the cables themselves.

This fact emphasizes the desirability of using in all future installations cable in which the "internal" heat resistance is as low as possible. In this connection recent investigation has shown a marked difference in the heat conduction of paper-insulated cables, depending upon the kind of impregnating compound used. The use of vaseline to "short-circuit" the heat resistance of the air ducts, however, has been found to result in notable improvement.

ADVANTAGES OF USING FILLER BETWEEN CABLE AND DUCT

Increased Capacity.—With crude vaseline in the conduit, the copper temperature is reduced 14 per cent at a load of 325 amp., as shown by accompanying heating curves. This reduction in temperature will, of course, permit carrying 7 per cent more load for the same rise. The degree of effectiveness of the vaseline seems to increase at higher temperatures, as shown by slope of the curve. This, together with the elimination of "hot spots," as noted below, will allow a much higher operating temperature for the cable and a corresponding larger increase in capacity.

Elimination of "Hot Spots."—In addition to the more rapid dissipation of heat, a more even temperature was

obtained in the cable itself. A difference of copper temperature of $3\frac{1}{2}$ per cent on the same conductor at points 5 ft. (1.5 m.) apart existed without the filler in the ducts; with it this difference was reduced to 0.5 per cent. As the fundamental cause of many cable failures is overheating at certain "hot spots," such an equalizing of temperature is important. In connection with the present practice of some electric service companies of reinstalling old cable in which weak points are very likely to exist any additional factor of safety seems well worth obtaining.

Decreased Electrolysis.—It is believed that the use of the vaseline as an insulating medium surrounding the cable sheath will eliminate trouble due to electrolysis. Tests have been projected to prove this point.

Mechanical Protection.—The value of the vaseline as a means for preventing the mechanical abrasion of the lead sheath is apparent. Where such faults already exist the grease will be effective in preventing failures.

EXPENSE INVOLVED

Introduction of crude vaseline between the cables and ducts would be attended by considerable saving in many cases in Chicago not only in old duct lines but also in new construction. However, it would not be advisable to consider using it in the entire system of transmission. It would be especially beneficial on circuits which feed the loop district and are operated at maximum load nearly all day, or on certain tie lines that are very heavily loaded.

To replace the air space in stone conduit with grease when occupied with 250,000-circ. mil., 12,000-volt cable will require about 1.5 lb. per ft. (2.23 kg. per m.) of duct length. At 4 cents per pound (8.9 cents per kg.), allowing 2 cents per foot (6.6 cents per m.) for labor, the total cost of introducing filler will be in the neighborhood of 8 cents per single-duct-foot (26.2 cents per single-duct-meter). Assuming an actual circuit having a length of 50,000 ft. (15,240 m.), the investment represented, at \$1.80 per ft. (\$5.90 per m.) for the 250,000-circ. mil. cable, 25 cents per single-duct-foot (82 cents per single-duct-meter) for conduit, and \$3,000 for operating apparatus at generating and substation ends, is \$111,000. To obtain 7 per cent increased capacity with new equipment would cost \$7,770, whereas obtaining it by using vaseline filler would cost only about \$4,000, an approximate net saving of \$3,770. On the basis of increasing the capacity of fourteen lines by 7 per cent a net saving of one line could be realized, where such a large group of parallel lines is required.

Magnets Recover Sunken Pig Iron

The Arrow Transportation Company, operating barges on several Southern rivers, lost one barge in the Tennessee River near Paducah last March. This barge, loaded with 420 tons of sand-cast pig iron, collided with the pier and dropped its load gradually. The loss represented about \$10,000, and the insurance company paid this to the transportation company. The insurance company arranged to recover what it could by means of a lifting magnet purchased from the Cutler-Hammer Manufacturing Company, Milwaukee, and approximately 400 tons were recovered. Because of the rising cost of pig iron it was sold for \$16,000. Total cost of recovering amounted to \$4,000.

Raising Wages with Cost of Living—II

A Plan for Paying Workers in the Electrical Contracting Industry on the Basis of Living Cost as That Cost Is Indicated by Index Numbers of Responsible Commercial Organizations

BY L. K. COMSTOCK

This is the second and final article on the views of Mr. Comstock on this vital topic, first presented before the Conference Club and published here because of the critical character of the relations between capital and labor.

FOR years it has been a common practice to trace general commodity price tendencies and reduce them to a common number called an index number. This index number is indicative of general tendencies and takes due account of both the simultaneous rise and fall of different commodity prices and their proper weighting. There are several institutions producing these index numbers monthly, and they are in general agreement, although developed in different ways.

A cursory examination shows that seven series of index numbers, made by five independent organizations, have a marked family resemblance. The testimony concerning the major facts of price fluctuations from these seven different sources is so unanimous that one can scarcely doubt its validity.

PRICES LIKELY TO CONTINUE TO RISE

In thinking of index numbers it should be remembered that during the last twenty years throughout the gold standard world the general level of prices has been rising, or, in other words, the purchasing power of gold has been falling; that all indications point to the continuation of this tendency for many years to come, and that this progressive shrinkage in the purchasing power of gold is a serious menace to the stability of business, disturbing the normal relations between those forms of income or prices which are relatively fixed, such as interest, rent, salaries and wages, and those which are more promptly adjusted, such as the prices of most staple commodities.

It is entirely within the possibilities that prices may rise more and more slowly until many years hence we shall see the culmination of this rising price epoch unless in the meantime wonderful new gold fields are discovered. The synthetic chemist and the electrical engineer may, of course, check this rising tide of prices in spite of any failure to discover new gold deposits sufficiently large to be effective. The generation which succeeds in producing flour and meal and sugar cheaply, by a synthetic process, will have made vastly more progress in world production than the nineteenth century made when it added the Mississippi Valley and the Canadian and South American plains to the world's producing areas.

Rising prices are by no means an unmixed evil; for a prolonged period of rising commodity prices energizes the business world generally, operates to the advantage of debtors and of owners of production processes, and to the disadvantage of creditors generally, of wage earners, of salaried persons and of receivers of fixed incomes; causes interest rates to rise, lessens the severity of crises and the duration of depressions, and stimulates social reconstruction.

During the decade 1899 to 1909 the general price index rose from 99.5 to 130, an increase of over 30 per cent. In other words, the commodity price level went up faster than the money earnings of labor, according to the figures prepared by the Bureau of Labor Statistics; and hence the real annual returns of labor showed a decline, slight in some trades but large in others. The evidence, then, indicates that all the intrenchments of organized labor, all the legislation in favor of the laboring classes, have failed to prevent the downward trend of commodity wages.

To consider specifically the application of such an index number to the wage scale of the New York Electrical Workers' Union, let us assume a base or par rate of wages, arrived at by mutual agreement, say, for instance, \$5.20, which is the rate that went into effect April 1, 1917. Dun's index number on that date was \$190.012. Let us assume that wages shall be readjusted once in six months. Dun's index number of Oct. 1, 1917, six months later, was \$219.679, or an increase in general commodity prices of \$29.667, or 15.6 per cent.

On the authority of the Bureau of Labor Statistics, the wage earner spends three-quarters of his wages for food, clothing and rent and other things responding to these general price fluctuations; he would, then, set aside \$3.90 out of the \$5.20 for subsistence. The index number for the end of the six months' period indicates that subsistence costs 15.6 per cent more; therefore increase \$3.90 by 15.6 per cent, making it \$4.50, to which should be added the quarter of the base rate not affected by the commodity market, \$1.30, thus making the readjusted rate \$5.80, or a net advance over the base rate of 60 cents per day.

The corresponding Bradstreet numbers are 14.5769 and 16.9117; the difference, 2.3348, shows an increase in the index of almost exactly 16 per cent. Applying this number as before, the adjusted wage is \$5.824, or an advance of sixty-two and four-tenths for the six months' period ending Oct. 1, 1917.

Let us examine the rate of wages of the New York Electrical Workers' Union from the index number point of view over a longer period of time, beginning with the year 1900. The rate in 1900 was \$3.50 per day. The Bradstreet index for that year was 7.88. The average monthly index for eleven months of 1917 was 15.4595. The difference between the two indexes, 7.5995, shows an increase in 1917 of 96 per cent. Increasing three-quarters of the 1900 rate by 96 per cent (\$2.52), the corrected rate for 1917 would be \$6.015, or, in other words, the purchasing power of a wage of \$3.50 in 1900 is just equal to the purchasing power of a wage of \$6 in 1917.

RELATION OF WAGE INCREASES TO CONTRACTS

It may be argued that a periodic adjustment every six months would interfere with contracts in course of execution. Let us admit this objection and at the same

time analyze it. If no allowance were made in estimating future work for the contingency of an unknown advance in the rate of wages due to the change in the index number, then under the conditions specified above the advance of 60 cents would cost the contractor 3.9 per cent, assuming the labor to be 35 per cent of any given contract, or 2.78 per cent, assuming the labor to be 25 per cent of any given contract.

INCREASED LABOR EFFICIENCY A FACTOR

An advance in the rate of wages which apparently increases the cost to the employer 3.9 per cent would be, in my judgment, more than offset by an increased labor efficiency; because the employee would be appreciative of the spirit of co-operation reflected by the adoption and practice of a plan of wage adjustment calculated to protect him against advances in the cost of living, and he would, consciously or unconsciously, respond to such an effort at practical co-operation on the part of his employer.

It should be stated, however, that in the example cited above the index number used might not be quite accurate in this particular application, because it is composed to some extent of factors which affect the cost of living only vaguely and indirectly. This number, for instance, gives the aggregate prices per pound of ninety-six different articles, including not only all kinds of food products, but also thirteen metals, eleven chemicals and drugs, seven building materials, and also raw and manufactured textiles, coal and coke, mineral and vegetable oils, naval stores, and seven miscellaneous articles; but nevertheless it gives a broad general indication of the changes in general price levels, and so perhaps would be as applicable as an index number derived from the price movements of only foods, clothing, rent and fuels.

It may also be argued that this plan of wage readjustment would tend continually to raise wages even beyond the critical point at which the tendency would begin to slow down the industry. This objection leads to a consideration of the fundamental theory of wages.

Labor has a value because its services or products have a value. If the labor is mispent, the product is valueless, and in the long run the labor will be equally so. Labor secures a remuneration because it produces something for which people are willing to pay. In other words, wages depend on productivity. The wages of the laborer depend upon the value of his labor and not upon his wants. But wages vary with the standard of life, and anything which lifts the standard will raise the rate of wages. The highest standard, though, will not prevent wages from falling in the face of a decrease in the demand for the product and a decline in industrial prosperity. However, anything which tends to increase the productivity of labor will raise the rate of wages. Raising the rate of wages in the long run will raise the standard of living, and in general a higher standard of living reflexively raises the productivity.

This being so, we can safely leave this objection as being one which might as well apply to the present method or any other method of readjusting wages.

It will be argued that union men will not be content with a relatively constant wage position in the economic world; that they will demand also an absolute advance, an advance beyond the point indicated by an index number. As long as the national wealth tends to increase

faster than the population, this demand on the part of union labor will be justified and will be justified in some more or less definite ratio to the increase of national wealth. This is the laboring man's only way of participating in an increased national wealth, national surplus, in the creation of which he has had so large a share. The demand for an absolute increase on the part of any particular trade, however, will be restrained by force of public opinion and by economic forces if such a demand is out of step with the demands of other trades requiring equal or similar skill.

Some may say that the advance in wages in the electrical trade has been absolute instead of relative, and they may point to the wages of the Chicago union as an example. Let us analyze this case from the index number point of view. In 1907 the wages in Chicago in the electrical trade stood at \$4 per day. The Bradstreet index number for 1907 averaged \$8.90. On Sept. 1, 1917 the index was 16.6441, and the average index number for twelve months of 1917 was 15.655.

Applying as before the average index number for 1917 to this case, we find that a \$4 wage in 1907 would be equivalent to \$6.28 in 1917. If, however, we compare the average index number for 1907 with the index number for Sept. 1, 1917, when the \$6.25 wage took effect in Chicago, we get a wage of \$6.61, which shows how conclusively the \$6.25 wage is justified and also that there has been no absolute advance whatever.

By the intelligent application of some such plan as the one outlined, there will result as a matter of fact an absolute advance in wages to the union man, due to the fact that he will work more days in the year when and because wage disputes are eliminated. This absolute advance is not one in the economic sense, but purely in the personal sense.

After all, any discussion of the wage question, if confined to the rate of wages per day, is inadequate and superficial; the yearly income is the only important desideratum for a wage earner, as it is also for any person whose income takes any other form.

FIXING THE BASE RATE OF WAGES

There remains the more difficult problem of scientifically fixing the base rate for wages. This is a much more complex problem than applying an index number to raise or lower the base. It would probably be sufficiently correct to assume any present wage as a base rate; it would certainly avoid endless discussions and fruitless speculations on the cost of keeping an average family. Probably all parties concerned would rather avoid the question by arbitrarily accepting the existing rate than to create a new rate, however scientific.

The United States Bureau of Labor has selected the years 1900-1909 for striking an average to serve as a base, or par, for developing its index number. Commodity prices for this period are averaged for the ten years and the result is called 100. If the weighted average of basic commodity prices is 3 per cent higher for 1913, the index number for 1913 is + 3 or 103. A base or par rate of wages could similarly be established from the prevailing wages during the same ten-year period and in as many localities as might be found desirable. Wages could then be adjusted from this par periodically by comparing the index number corresponding to par with the index of the next period preceding the time selected for adjustment.

Liberty Loan Sale Stimulants

The Use of the Spirit of Competition Within the Company to Produce 100 per Cent Participation—Bulletin Boards, Thermometer Charts and Other Methods for Keeping Up the Interest of Employees

IN TWO weeks the national campaign on the third Liberty loan will open, to continue for three weeks. As was pointed out last week, the success of this loan lies not wholly in the total subscription but to a considerable extent in the number of people participating.

To a large extent, therefore, the employers of labor are in a position to make this the most successful of the three loans. Employees must be made enthusiastic

FIG. 1—A TYPICAL GRAPHIC CHART SHOWING PERCENTAGE OF EMPLOYEES SUBSCRIBING

—made to understand why they should lend their money to the government. Plans, therefore, must be laid to insure a 100 per cent subscription in every plant, shop and office in the electrical industry.

An investigation is being made by the ELECTRICAL WORLD of how other employers have interested their help in the preceding loans in order to give to the industry the best results of the experience of others.

Last week the necessity of getting together a committee of the men was emphasized. This week another preliminary step is to be developed—making a plan to stimulate interest throughout the campaign.

Because of the human element in every man, the competition method of sustaining interest is the most common one and the one which is most uniformly successful. Under this method departments can be played against each other or any other division of employees that naturally suggests itself very effectively. Where there are a number of district offices this plan can be followed out between offices.

In using this competitive plan the ultimate goal must be kept well in mind—namely, not total subscriptions, but 100 per cent participation. Therefore the tally

sheets should not record the total subscription, but the percentage of employees taking bonds. This places every department on a more equitable basis for running a race with the other departments.

Undoubtedly the most effective way of keeping these tally sheets is by graphic charts. Fig. 1 shows a suggestion for a company with but one department or where it is decided to hold no intra-company competition. Obviously the idea is to do better in the percentage of employees participating than in either of the first two loans with the bogies set at 100 per cent. This chart should be corrected daily by some authorized person and placed in as conspicuous a place as possible. Those selected to make a personal canvass of employees can make one of their appeals on the basis of the chart.

INTRA-COMPANY COMPETITIONS

If an intra-company competition is undertaken, the chart idea can be carried out much more logically. With one tally master to see that the score is kept right and corrected daily, each participating team or department, or whatever the division may be, is plotted in terms, not of dollars, but of percentage of members subscribing, no matter how small or how large the

FIG. 2—CAMPAIGN THERMOMETERS HAVE A STIMULATING INFLUENCE

subscriptions. The race then is to see which will first reach the 100 per cent mark, or if none does so, which will stand highest at the end of the campaign.

In this manner a strong feeling can be aroused that will find a ready answer in bond subscriptions. Workmen are not apt to let another department go them one

better, particularly in patriotism, if it can be prevented.

As a further stimulus to a large participation, the employer can afford to allow a bonus of one dollar on every fifty-dollar bond for the members of the first department to reach the 100 per cent mark. Or there are other means. Following the lead set by the national committee, the first department to reach the goal can be presented with an American flag or some similar patriotic token, and this flag or token can be striven for in each succeeding campaign, the holders to keep it until defeated.

Along this same line the thermometer chart usually keeps interest up. In fact, with this type of chart, as illustrated in Fig. 2, the interest becomes more keen as the campaign progresses. As with the other charts, the thermometer method can be used for intra-company competition, using a separate thermometer for each participating team or department, etc. The thermometer is so arranged that the "mercury column" moves upward with the subscriptions.

Besides, the thermometer idea lends itself well to almost numberless catchy phrases embodying the idea of "making it hot for the Kaiser."

In the intra-company competition each participating department should have its own bulletin board showing how the individual members are signing up, and then there should be a master board at some convenient place in the plant or office or shop where the comparative standing of all departments is kept.

As there are only two more weeks left before the campaign starts it is well to see that all preliminaries have been taken care of. (1) Are all committees appointed and do they feel the right enthusiasm? (2) Have arrangements been made for an easily accessible, centrally located Liberty bond desk? (3) Have Liberty loan buttons or other means of designating a subscriber been procured? (4) Are the subscription blanks on hand? (5) Have arrangements been made for bulletin boards? (6) Are the charts or "thermometers," etc., ready? (7) Have arrangements been made for a sufficient supply of Liberty loan literature? (8) In fact, is everybody ready to make the third Liberty loan a 100 per cent success?

Other ways of selling bonds to employees will be described next week, and a plan to steady labor conditions by aid of the Liberty loan will also be described.

Output of Large Generating Systems

Great Growth in Use of Central-Station Energy Shown by Returns from Forty-seven Companies in United States and Canada—Increase More than 4,000,000,000 Kw.-Hr. for Year

THE usual statistics for 1917 on the outputs, peak loads and load factors of the largest generating systems of the country are given on the opposite page. The list has been expanded so that it now contains every generating company in the United States and Canada having an output of more than 100,000,000 kw.-hr. per annum. The aggregate output of the companies listed was 21,000,000,000 kw.-hr., of which the companies operating in Canada generated 3,500,000,000 kw.-hr.

Although the greater part of the electrical energy was generated from water power, it is of interest to note that almost all of the hydroelectric systems having steam reserve stations were obliged to use them during the year. This is indicative of the necessity for further water-power development if our fuel resources are to be conserved. For instance, the great hydroelectric systems on the Pacific Coast had to resort to steam to meet their demands as follows: Pacific Gas & Electric Company, 195,000,000 kw.-hr.; Southern California Edison Company, 144,000,000 kw.-hr.; Southern Sierras Power Company, 7,000,000 kw.-hr.; Portland Railway & Light Company, 23,000,000 kw.-hr.; Puget Sound Traction, Light & Power Company, 5,400,000 kw.-hr.

These statistics show clearly how baseless is the assertion that these systems are overdeveloped hydraulically. The shortage of hydroelectric energy at Niagara is well indicated by the large output that the Buffalo General Electric Company was called upon to turn out in its steam-driven station, where approximately 130,000,000 kw.-hr. had to be manufactured from coal. The dearth of water power is also indicated in the outputs of the Southern power companies, the

Tennessee Power Company turning out by steam over 84,000,000 kw.-hr.; the Alabama Power Company, 41,000,000 kw.-hr., and the Georgia Railway & Power Company, 22,000,000 kw.-hr. Other hydroelectric companies which had to fall back on steam equipment to carry their load were the Adirondack Electric Power Corporation, 51,000,000 kw.-hr.; Rochester Railway & Light Company, 51,000,000 kw.-hr.; New England Power Company, 54,000,000 kw.-hr.; Wisconsin Edison Company, 77,000,000 kw.-hr.; Electric Company of Missouri, 112,000,000 kw.-hr., and the Minneapolis General Electric Company, 75,000,000 kw.-hr., all of which merely confirms the need of further water-power development.

Only one company in the entire list shows a slight decline in output over that of the previous year. All the others show increases, and considering the enormous outputs involved and the handicaps under which the central-station industry was operated during 1917, the showing is phenomenal. All the Canadian companies show large increases, due chiefly to the great demand made for power by war industries. The same is true of many of the Eastern power companies, as, for instance, the Public Service Electric Company, Detroit Edison Company, Philadelphia Electric Company, Cleveland Electric Illuminating Company and the Consolidated Gas, Electric Light & Power Company.

It will be appreciated that there is some duplication in the returns of some of the companies which purchase energy from other sources and include the purchased energy in their returns. For the sake of convenience, similar statistics for the years 1915 and 1916 are published side by side with the statistics for 1917.

STATION & OPERATING PRACTICE

A Department Devoted to Problems of Installation, Operation and Maintenance of Equipment for Economical Generation and Distribution of Electrical Energy

CAUSE OF TROUBLE WITH SINGLE-PHASE STARTER

Often Due to Poor Contact Between Moving Contact and Stationary One Connected with Resistance and Reactance

BY E. C. PARHAM

When trouble with single-phase starters having connections like those shown herewith occurs it will usually be found that the contact *a* fails to touch both *b* and *b₂*, or that there is an open circuit in the leads between

SIMPLIFIED DIAGRAM OF SINGLE-PHASE STARTER CONNECTIONS

these contacts and the motor. Failure of *a* to make contact with either *b* or *b₂* may be due to a weak spring or blistered contacts. If any of the faults mentioned exist, the production of a split-phase for starting the motor is prevented.

THE SYSTEM LOAD FACTOR VERSUS STATION LOAD FACTOR

Study of Operating Conditions in an 18,500-Kw. Turbine Plant—Cost of Coal and of Hydroelectric Energy

In making up operating data from central stations where energy is purchased in considerable part a distinction should be made between the system load factor and the station load factor. A study of operating conditions in an 18,500-kw. turbine plant producing 40,507,750 kw.-hr. in 1917 was recently completed. The yearly load factor of the station on the basis of an average output of 4625 kw. and a maximum peak of 14,000 kw. was 33 per cent. Incidentally the coal consumption per kilowatt-hour was 2.64 lb. (1.197 kg.) and the net cost of production at the bus-bar was 9.21 mills for locally generated energy. Coal cost 5.73 per ton at the plant, with rail delivery, and bituminous coal of high grade was burned under boilers equipped with mechanical stokers.

This company, however, purchased 10,670,650 kw.-hr. from a hydroelectric system traversing the State, so that the average load on the system was increased to 5850 kw. and the load factor, assuming a common point of supply, was raised to 41.6 per cent. The net cost of delivery of each kilowatt-hour to the system from the local plant and from the wholesaler of energy was \$429,571, or practically 8.5 mills per

kilowatt-hour. The hydroelectric energy supplied cost about 5.3 mills per kilowatt-hour. The central-station interchange contract with the hydroelectric company resulted in the sale by the former to the latter of 365,400 kw.-hr., at 8.05 mills per unit; but in the main the supply of energy from the water-power system was sufficient to make it necessary to furnish supplementary service only occasionally.

OPERATING A FURNACE WHILE MENDING STOKER

Chain-Grate Stoker Is Backed Out and Temporary Bridge Wall and Brick Front Constructed to Permit Firing

In the power houses of one of the Illinois state institutions where inmates were used as firemen, two 400-hp. stokers failed completely owing to the warping of the shaft at the rear ends of the grate. These stokers were backed out of the furnaces and temporary bridge walls and temporary fronts of brick were placed as shown in the accompanying illustration. Old plain grates secured from other inoperative plants were secured and laid on this foundation of brickwork so that the boilers could be fired by hand through an opening left in the brick front. This opening was closed when

PIPES RESORTED TO FOR GRATE BARS WHILE AWAITING REPAIR PARTS

the men were not firing by a perforated piece of sheet iron which had holes enough in it to keep it from getting red hot.

While the foregoing method of repairing and operating a boiler is not recommended for prolonged service, it did meet an emergency and kept the plant running until the delayed repair parts were received and placed in service.

ESTIMATED TOTAL COST OF SEMI-OUTDOOR SUBSTATION

Consists of an Outdoor Transformer Station and an Indoor Converting and Distributing Station—Will Energize City Street Railway

In the accompanying table the estimated total cost is given of a semi-outdoor substation now approaching completion in Massachusetts for the supply of energy to a Springfield urban street railway from the Turners Falls Power & Electric Company system at 66,000 volts.

TOTAL COST OF SEMI-OUTDOOR SUBSTATION IN MASSACHUSETTS

OUTDOOR TRANSFORMING STATION	
Two 6000-kva., 66,000-13,200-volt transformers (\$2.08 per kva.)	\$25,000
Two 66,000-volt lightning arresters	5,000
Four 66,000-volt oil switches	10,800
Seven 66,000-volt disconnecting switches	1,400
Foundations for equipment	2,000
Copper tubing and insulators	1,174
Water pumps, tools and piping	7,000
Labor of installation	2,100
Engineering and contingencies, 20 per cent.	10,894
Total	\$65,368
INDOOR CONVERTING AND DISTRIBUTING STATION	
Building and foundations, 50 ft. by 70 ft.	\$50,000
Three 1500-kw. motor-generator sets (\$22.22 per kw.)	91,000
Switchboard, thirty-six panels	25,800
Wire, cable and conduit	15,000
Labor of installation	5,500
Engineering and contingencies	37,460
Total	\$224,760
Grand total (\$24.18 per kva.), initial transformer capacity	\$290,128

The exterior equipment includes two 6000-kva. transformers and necessary oil switches, "disconnects" and auxiliary equipment, with lightning arresters mounted on concrete bases in the substation yard. Inside a brick and concrete substation building are three 1500-kw. motor-generator sets, receiving energy at 13,200 volts alternating current and delivering direct current at 600 volts to the local trolley lines.

RELIABILITY OF METHODS OF TESTING GROUND RESISTANCE

Bureau of Standards Opposes Lamp-Bank, Fuse, Single-Voltmeter and Magneto Methods of Testing and Recommends Kohlrauch Bridge

After a series of extended experiments on testing the resistance of ground connections, the Bureau of Standards has come to the conclusion that most of the methods commonly used do not give correct results. Dependable results can be obtained by use of the ammeter-voltmeter method when a proper selection of instruments is made. The disadvantages of this method, however, are the non-practicability, the possible absence of energy supply, the amount of calculation required and the necessity for two auxiliary grounds or one of assured low resistance. If a potential as high as 600 volts is available, direct current may be used as efficiently as alternating current, but this method must be discarded if other ground connections than those to be investigated exist.

A direct-reading, portable, rugged and fairly reli-

able means of testing the resistance of ground connections is found in the use of the Kohlrauch bridge method or a modification of it. A separate source of energy may be obtained from a dry cell, and two auxiliary grounds must be available. Actual practice shows that the Kohlrauch bridge method checks with the ammeter-voltmeter method to within an average of 3 per cent. The error very seldom approaches 10 per cent.

The present-day methods of ground testing used by many electric companies have been found very unreliable. These methods consist chiefly of the lamp-bank, fuse, single-voltmeter and magneto methods. The results by these methods are not even approximately correct. The single-voltmeter method gives a degree of accuracy that depends largely upon the resistance of the voltmeter and possible fluctuations in the voltage of the line.

An extensive study of the effect of high voltage upon the electrode and the surrounding soil showed that the energy liberated at first causes the resistance to decrease about 20 per cent. If the critical value is reached, the soil will commence to dry out and an increase of resistance will follow. It is necessary, therefore, to read the meters immediately on the closing of the circuit.

INEXPENSIVE CORNER FOR LINE WITH MANY TURNS

Right-of-Way Difficulty Solved by Designing Special Inexpensive Type of Corner Construction

The 33,000-volt, three-phase transmission-line corner construction shown in the photograph reproduced herewith was designed especially for a 12-mile (19.3-km.)

TURNING CORNER ON STRAIN INSULATORS SAVES EXPENSE

line in which there are seventeen turns. When the right-of-way was being purchased it was found necessary either to follow this devious route or to pay exorbitant prices for pole rights for a straight run between the plant and end of the line. According to the engineering estimates, this type of corner is about 75 per cent cheaper than a two-pole corner and is approximately 70 per cent cheaper than a buck-arm corner of single-pole construction. The guying for any one of the three types of corners would be practically the same, but the large difference in cost would come in the reduced labor and material charges entering into the construction at the top of the pole.

REMOTE-CONTROL AIR-BREAK SWITCH OF INEXPENSIVE TYPE

Operating Force Imparted by Weight, and Control Impulses Are Electric—Details of the Method of Construction Followed

The San Diego Consolidated Gas & Electric Company has recently utilized remote-control mechanisms to operate air-break switches employed on its 11-kv. distribution lines. Type 1420, style 5008, made by the Pacific Electric Manufacturing Company and rated at 100 amp., 20 kv., are used. The operating handle has been replaced, however, with a distant-control mechanism mounted in a box on the pole, the operating force being imparted by a weight and the control impulses by electricity.

As the switch mechanism is designed primarily for use as switching centers on long suburban 11-kv. feeders, in districts where the only available supply of energy is from the very feeder to be controlled, it was seen at once that motor or solenoid operated mechanisms were out of the question, since the expense of an auxiliary source of supply would be excessive, while if such supply were not furnished, the switch might prove inoperative because of failure in the line at the very time it was most needed.

The mechanism consists of a cast-iron pulley wheel, to which the wooden switch-operating rod is attached eccentrically and over which the chain supporting the weight is passed. As the operating impulses are imparted to triggers, the wheel is repeatedly released and arrested, and after each impulse is caused to rotate through a half revolution by the weight. With the rod-attachment point in the upper position the switch is closed; when in the lower position the switch is open, the wheel giving the same throw to the rod as would be imparted by an operating lever when switched by hand control.

It will be noted that at the beginning of each movement the motion of the end of the lever is perpendicular to the normal operating motion, which gives the weight an opportunity to gather momentum and apply the necessary force to open or close the switch properly. At the end of the stroke the motion is similarly retarded, and the large spring interposed between the weight and the chain further takes up the jar of the arrested weight. The chain is endless, and consequently the balance is not changed after successive operations. The weight is attached to the chain by a hook device, and the switch is rewound after several operations by detaching the weight and rehooking it to the chain higher up. Six or eight successive operations are possible (depending on pole height) before the switch requires rewinding, this being as many movements as will ordinarily be desired before an opportunity for re-setting presents itself. An old arc-lamp reel and pulley is provided and the weight can be raised by one man.

The trigger system is designed to give positive operation with small direct-current impulses. For this reason a double system of levers is employed. The turning movement of the weight is resisted by secondary levers, so that there is very little friction on the primary triggers. After release each lever is returned to position by a coil spring. The tripping mechanism is mounted in a heavy poplar box, with top and end hinged to permit ready inspection. A lineman may trip the switch

by hand manipulation of the triggers, or if desired a pair of tripping cords can be run down the pole.

The tripping solenoids are series coils from old arc lamps. A small 24-volt storage battery at the distant control point furnishes the momentary direct-current impulses to operate the switch. A pair of contacts is also provided on the main shaft to operate pilot lamps at the control point, thus affording a return signal to prove the operation of the switch. As the operating current is only momentary and a small switch is provided in the lamp circuit so that the lamps are lighted only during switching or testing operations, the draft on the battery is small and it need be recharged only at considerable intervals. The remote-control operating switch is a double-throw knife switch with positions properly designated "open" or "close." Throwing of the master switch to the wrong position will not affect the

AUTOMATIC AIR-BREAK SWITCH, WITH DETAILS OF OPERATING MECHANISM

tripping mechanism. In order to have the indicating lamps entirely independent of the tripping circuits, five wires are run between the switch and the control point. The switch is tested monthly on a Sunday morning, so as to keep all contacts free.

The switch was designed primarily for use at important switching centers and test points. For instance, in one case an 11-kv. feeder, after passing through several small towns, spreads out over an extensive agricultural district covered with many line hazards in the way of trees, river crossings, brush-fire hazards, etc. A switch of this type is installed beyond the largest town, and the control is installed in the home of the district troubleman near by. In case of trouble on the feeder the line may be quickly sectionalized at this point, and if the trouble is beyond in the agricultural district, as is usually the case, service may be immediately restored over the more important part of the circuit. Considerable time is saved, particularly at night, over the old hand operation, and if the troubleman is absent on his regular duties, his wife may be called on in emergency. In quickly restoring service and in line testing this non-automatic switch is a great improvement over fuses, and in fact it practically replaces a far more expensive automatic oil switch.

EDUCATING WOMEN IN CENTRAL-STATION WORK

Meeting in Los Angeles Shows Method Adopted for
Giving New Help a General Knowledge
of the Business

That women are more and more making a place for themselves in the conduct of public utility business is recognized. Of late the war has called so many men that women have been forced into utility work that they could probably otherwise have had difficulty entering for years. An evidence of how women are beginning to take hold and how they can quickly be given a general knowledge of the business is contained in the following report of a meeting of 150 women employees of the Southern California Edison Company, Los Angeles, which was held a short time ago. Those who were present are employed in the company's offices in Los Angeles and the adjacent cities. Probably 100 of the company's woman employees were not able to attend on account of distance or other reasons. Only seven or eight men were invited, and they were officers of the company.

The object of the gathering was to inaugurate a series of meetings to be held at regular intervals by the company women, and it is the intention to invite to each meeting one or more officers or department heads, who will address the women on subjects which are to be agreed upon later, but all pertaining to the affairs of the company and the best way to handle them. Miss Gertrude Tucker presided, and in her opening remarks explained that many vacancies had occurred in the executive, commercial and engineering departments during the past year because of the war and that a considerable number of these positions had been filled by bringing into the organization many capable women. Woman's work in the company was increasing every month, not only because of the greater number of women employed, but also because women were filling the positions which had heretofore been reserved exclusively for men.

These meetings are for the purpose of informing the newer women employees as to the history and traditions of the company and educating them as to the company's responsibilities, aims, ambitions and expectations. At future meetings one of the officers will tell of the number and variety of companies which have been consolidated in past years to make the Southern California Edison Company of to-day. Another will tell where the power comes from and where it goes to; another will explain where the money comes from and where it goes to, and still another will tell where the 175,000 consumers are and how they are looked after. Others will discuss such matters as departmental work, taxation, regulation and kindred subjects—all to be treated in an interesting, understandable and non-technical manner.

THE CREDIT DEPARTMENT'S RELATION WITH CUSTOMERS

Methods Adopted by Large Utility for Obtaining
Credit Information and Light and
Power Deposits

When every dollar means so much, when losses must be minimized, the necessity for stricter credits becomes apparent. The credit department of a central-station company therefore occupies a much more important position than formerly. Strict methods calculated to keep down losses are all the more desirable. Such methods are outlined in the following statement showing how a large Middle Western utility takes care of its customers' credits.

TWO CLASSES OF CONTRACTS

Commercial contracts are received in the credit department from the contract department, and on receipt are stamped on a receiving time stamp showing the exact time of arrival in the department. They are then checked off in a receiving book, which is an index as to whether or not the contracts have been received or are being held in the department. The credit slip attached to each contract then receives a number similar to the contract, by which it can be identified later on should it become necessary to refer to it. After a careful examination of the signature on each is made, the contracts, which may be divided as class 1 and class 2, are handled in the following manner:

Class 1—Applications from those claiming to be former consumers and giving address of former location as reference. The account is looked up to ascertain the customer's habit of pay and to find out whether the account is paid up to date. If the investigation proves satisfactory, the application is passed without further delay. If, however, the customer has paid penalty month after month, or if it has been necessary to cut off his service in order to force payment, a deposit for the new address is required.

When a deposit is necessary the customer is so notified by letter and the application is held pending its receipt. Upon receipt of the deposit a deposit certificate is issued and mailed to the depositor and the application is approved for service. When more than the current bills at the previous address are found owing a statement is sent the customer, with a letter notifying him that no service will be given until payment is made. The account in arrears is noted "Notify credit department when paid," so that in the event of the payment crossing the letter in the mail, the bookkeeper will advise of receipt of payment at once and thus avoid unnecessary delay. The application is filed in the holding file, and no service given, until account is paid.

Class 2—Applications from those claiming never to have used company's service. This class of applications

is looked up in the suspense file to ascertain whether the applicant has not overlooked a previous address where service has been used and a balance remains unpaid. If the suspense file discloses such an account, the applicant is advised by letter of such indebtedness and payment requested, the application being held and no service given until payment is made.

DUPLICATE COPIES OF APPLICATIONS

When the suspense account discloses no indebtedness, rating books are consulted, in some cases special reports from the rating agencies are obtained, or references offered as to the responsibility and credit standing of the applicant are investigated. Should the investigation prove unsatisfactory, a deposit is requested which is equal to two months' bills, the amount of the bills being estimated by installation, location and class of business. This deposit is requested by letter and the application filed in the holding file until received.

Owners of real estate in good standing are passed after claim of ownership has been verified. Applicants who object to making a cash deposit can furnish a guarantee from a real estate owner in good standing, or from a responsible business man, guarantor being required to sign a form adopted for this purpose.

A duplicate copy of all resident applications taken in the contract department is received in the credit department each morning. On these applications the service has been given before the credit has been passed so as not to inconvenience the applicant while credit is being investigated. On receipt of these duplicate copies of the application the same routine is followed as with the commercial contracts. When deposits are required which the applicant refuses to pay service is disconnected and the meter removed in a manner to be explained further along.

All letters requesting a deposit or unpaid balance have two carbon copies. One of these copies is attached to the application and filed in the holding file and the other is filed in an every-day file seven days after date. When these copies are reached they are checked with the holding file, and in all cases where the request has been complied with the copies are destroyed, but those from whom there has been no reply receive a second letter calling attention to the first one and requesting a reply. These second letters also have two copies, one of which is attached to the application and returned to the holding file and the other placed in the every-day file seven days ahead. If no response is had to this letter at the end of seven days, the application is removed from the file, and if the applicant has no service at the new address it is canceled and returned to the contract department.

Where a deposit is found to be necessary from applicants for commercial lighting who move into a location where light is already installed and in use, and for all resident applications where service has been turned on before credit is investigated, a shut-off notice is made out at the time the first deposit letter is written. This shut-off order instructs the shut-off collector to call and obtain the deposit or disconnect the service. When the collector calls, unless deposit is received or a good reason given for its not being made, or satisfactory information as to the applicant's credit standing given, service is discontinued. These cut-offs are held ten days, and if the applicant does not call or make some attempt

to satisfy credit, the meter is ordered removed. When the repair department reports back that the meter has been removed the application is canceled and returned to the contract department.

In all cases where commercial applications are held in the credit department the contract department is notified at once why application is being held, and in cases where the applicant is the successor and the service has not been discontinued for the predecessor, status slip accompanies the notice requesting that the successor be billed from the date of his application.

When a final bill is rendered and not paid a statement is made out in duplicate by the collection department and a duplicate copy is sent to the credit department where a record is taken of it on a card and the card then filed in the suspense file. Where the delinquent is a corporation or partnership the credit slip received with the contract is referred to, and the officers' or partners' names and addresses are ascertained and a card made in each of their names, with a notation thereon to refer to the card for the company of which they are members. The duplicate statement is then stamped "Suspense" and returned to the district head in charge of collections, to be used as a check on the collector. The statement is then worked by the collector, and a report of his calls and their results is noted on the reverse side. Should the statement be collected or paid at the office, the statement is returned to the credit department so noted, and the card is withdrawn from the suspense file and destroyed. Should the account prove uncollectible and it be found necessary to send to an attorney, the statement of the collector, with his reports noted thereon, is returned to the credit department and any information of value obtained by the collector is transferred to the suspense card to aid in the collection of the account later if opportunity arise.

The value of the suspense file depends in large measure on obtaining the applicant's full first name. If the customer insists on signing the first initial only, he may be allowed to do so, but effort is made to find out what the initial stands for and to note this on the application. The number of suspense cards made out and filed by this company averages approximately 3500 per month, and the average monthly revenue obtained from this file during the past year amounted to \$800, or almost \$10,000 in the course of the year.

HANDLING MERCHANDISE SALES ORDERS

Merchandise sales orders are handled as are light and power applications. Many firms are trading on open account with this company, and some accounts must be watched closely, letters being continually written requesting payment on slow accounts, and in a few cases credit being stopped completely pending settlement.

A card file is kept in the department showing customer's name, service location, date signed, the predecessor's name if it is a successor application, the name of the company's agent obtaining the business, and the order number of the contract, which number agrees with the number on the credit slips. Another file is kept which shows all deposits of record, by whom made and for what address, and still another file for line extension advances, which are taken by the credit department and either applied on the light and power account, if the customer is a consumer, or transferred by journal entry to a holding account.

SALES BULLETIN FOR ALL THE EMPLOYEES

Sheet Designed to Help Those in Every Department to Turn in Domestic Business on Commission Basis

In its endeavor to increase the sale of electrical energy in the home through a more liberal use of appliances the Public Service Company of Northern Illinois has started publishing what is known as the *Public*

SALES BULLETIN

ANNOUNCEMENT OF NEW SALES POLICY
Company to Pay Commission on Sales

Ladies and Gentlemen:
Meet Mr. Ironmonger.

This energetic little man, whom you see at your left, represents a commission of 5% which the Company will pay you on Gas and Electric Appliance Sales which you make. Now just a moment.

Don't all you at once!
We know you are not in the Sales Department; and that this is not a part of your work, and that you have had no experience in selling, and all that.

To begin with: It is not expected that you will neglect your regular duties to do sales work. This plan is based on the proposition that each one of our 2,000 employees has a certain number of friends, and neighbors, who are customers of the Company, and who they come in contact with from time to time.

If you will only take advantage of this opportunity to call their attention to one or more of the many gas and electric labor saving devices we have for sale, you will be surprised to see, "How easily a sale is made." And after each sale, Mr. Ironmonger will come around with the 5%.

Now as to Experience:
The first salesman that every lived, began without experience. His experience came only after repeated effort. Who can say but that in our organization of 2,000 employees, there are many potential salesmen and saleswomen.

Now is your chance to demonstrate your sales ability, and incidentally add to your bankroll. Opportunity in the person of Mr. Ironmonger is knocking at your door. It is up to you to let him in.

Inspiration is more likely to strike a busy man than an idle one.

Hustle will get you more than hushes.

Don't wait for opportunity. Go after it.

Be a Live Wire and you won't get stepped on. It is only the dead ones that are used for door mats.

SALES BULLETIN ISSUED MONTHLY FOR THE INFORMATION OF EMPLOYEES

Public Service Sales Bulletin. This one-sheet folder will be published monthly and will be distributed with the pay envelopes of the employees. The first issue contains an announcement that the company will pay a commission of 5 per cent to its employees on all appliance sales.

The rules governing the payment of these commissions to employees are as follows: All employees are eligible except division superintendents, assistant division superintendents, gas salesmen, industrial gas salesmen, electric salesmen, electric power salesmen and clerks in sales rooms. The commission of 5 per cent will be paid to all other employees on retail sales of gas and electric appliances, except gas ranges, gas stoves, incandescent lamps, fans and automobile-charging outfits, for use in the homes of customers of the company. The commission is payable as soon as the customer pays for the appliance, and in the case of deferred payment sales as soon as the customer has made the second payment. The commission will be paid monthly on or about the fifteenth of the month following the sale. The employee must obtain a signed order in duplicate from the customer on a form provided for the purpose. The employee must make sales

during his spare time or after the company's regular business hours. Employees must find their own customers; if they are unable to close the sale, they may, if they so desire, ask the division salesman for assistance, and by mutual agreement divide the commission in such cases. Appliances will not be placed on trial.

HYDROELECTRIC COMPANY ADVERTISES FUEL SAVING

Interesting Circular Points Out the Way in Which One Company in 1917 Saved 300,000 Tons of Coal

The Southern Sierras Power Company of California, in a concise circular entitled "Electricity's Part in Fuel Saving," recently gave its customers some interesting data on the saving which water power has made and can make in the amount of commercial fuel used in California. A copy of the circular distributed to the customers is shown herewith. It points out that in 1917 the Southern Sierras Power Company and associated companies generated 148,267,885 kw. of electrical

ELECTRICITY'S PART IN FUEL SAVING

So serious is the coal shortage throughout the United States that it has become the patriotic and imperative duty of each individual to aid to the utmost in the conservation of commercial fuel.

This can best be done by the use of electricity, generated solely by water power, which has the recommendation and approval of the government.

The generating of hydroelectrical energy requires no fuel.

Even the water turning the wheels of the enormous power plants operated by this company is not consumed or contaminated, but returns at once and without diminution to its natural channels. During the year 1917 the Southern Sierras Power Company and associated companies generated 148,267,885 kw.-hr. of electrical energy (all but 6 per cent of which was water-generated), which in its many uses is doing work in the mines, factories, farms and homes of this great Western territory that otherwise would have necessitated the use of 300,000 tons of coal. It would have required 7500 coal cars to have transported this vast quantity of coal to the consumers.

To curtail your use of electric service, or to fail in utilizing electricity to the very fullest extent in business and in your home, is to fail in doing your full share to support the government's fuel conservation policy.

There are many uses in every business and in every home for electric service where a direct and material saving of coal will result.

Electric cooking and electric ironing are important factors.

In residences, hotels and restaurants throughout this company's territory electric service is being used to-day for cooking, and by using electricity for this purpose these consumers are saving the government an equivalent amount of coal annually.

If our 11,000 consumers used electricity for cooking, the saving would be 150,000 tons of coal annually.

In practically every industrial pursuit in the West electricity is simplifying production, abolishing wasted effort, increasing production, cutting operating costs—and SAVING FUEL.

THE SOUTHERN SIERRAS POWER COMPANY

energy, all but 6 per cent of which was water-generated, and in so doing eliminated the necessity of the same power consumers using 300,000 tons of coal which it would have required 7500 coal cars to transport. The circular also points out that if the company's 11,000 consumers used electricity for cooking the saving in coal would amount to 150,000 tons annually.

TECHNICAL THEORY & PRACTICE

Including a Digest of Important Articles Appearing in
the Scientific and Engineering Press
of the World

Generators, Motors and Transformers

Periodical Insulation Tests.—P. M. LINCOLN.—The article contains replies from twenty-five out of about eighty electric service companies in twenty-seven states to the following questions: What companies apply potential tests to the insulation of their generators and other similar apparatus? (2) How frequently is such a potential test applied? (3) What test voltage is applied (measured in terms of normal operating voltage)? The main information was contributed by the Commonwealth Edison Company, the Niagara Falls Power Company, the Interborough Rapid Transit Company of New York City, the Edison Illuminating Company of Brooklyn and the Philadelphia Rapid Transit Company. Of the eighty replies received, seventy-five admitted more or less frankly that no attempt has been made to apply periodical high-potential tests to generator apparatus for the purpose of determining the condition of the insulation after the apparatus has once been placed in service.—*Electric Journal*, March, 1918.

Essentials of Transformer Practice.—E. G. REED.—Seventh installment of a series of articles on this subject. In the article the author discusses the initial rate of temperature rise, temperature gradient between windings and oil, heating and cooling curves, overload temperature-rise curves, and safe maximum operating temperatures.—*Electric Journal*, February, 1918.

Generation, Transmission and Distribution

Ground Connections for Distribution Systems.—W. C. HESTON.—The great cost of the prescribed ground for overhead distributing systems led a Portland company to experiment with various types of ground to see whether a less expensive method might not be found which would meet requirements. The results of these comprehensive tests and the conclusions drawn from them are presented in the article.—*Journal of Electricity*, March 1, 1918.

Long-Distance Transmission in Germany.—(Abstracts from data given by F. Niethammer in a recent issue of *Elektrotechnik und Maschinenbau*.) The author gives some particulars of the generation of electricity in Germany, which in 1916 amounted to 10,000,000,000 kw.-hr., as compared with 2,600,000,000 kw.-hr. in 1913, and discusses a possible electric network covering the entire country. The potentialities of water power are being much appreciated in Austria and Germany, and schemes are being promoted for the utilization of a large part of the power to be derived from waterfalls in the Austrian Alps. It is also stated that in the near future Germany aims at the complete electrification of all her railways and the erection of super-generating stations using power derived both from water and from the exploitation of her large fields of turf and bituminous coal. A still further development in the general industrial use of electricity in large cities

for heating, lighting and power is considered probable.—*London Electrician*, Feb. 8, 1918.

Combustion of Coal and Design of Furnaces.—HENRY KREISINGER, C. E. AUGUSTINE and F. K. OVITZ.—After several years of experiments in fuel combustion in a special furnace the Bureau of Mines, Department of the Interior, makes the announcement that from the results it has obtained it is possible to design a furnace with considerable more assurance as to its capabilities than has heretofore been possible. The process carried on in the combustion space is influenced by many factors, the most important of which are the volume and shape of the combustion space, the kind of coal used especially the character and amount of volatile matter it contains; the rate of firing, the quantity of air supplied over the fuel bed, the rate of mixing the air with the combustible rising from the fuel bed, the rate of heating the coal, and the temperature in the combustion space. The qualitative effects on the rate and completeness of combustion of many of these factors have been known for a long time, but the quantitative data presented in definite units of seconds, pounds, feet or percentages, have been lacking. To obtain such definite information a study of combustion in the space beyond the fuel bed was undertaken, and the results of extensive tests are given in this bulletin. About 100 elaborate tests were conducted in a special furnace using three kinds of coal—Pocahontas, Pittsburgh and Illinois—and at rates of combustion covering the full range found in practice. These are believed to be the most extensive tests of the kind ever undertaken. While the bulletin is especially for those interested in the design or reconstruction of fuel-burning furnaces it contains much of interest to the general engineer interested in fuel problems. Some of the statements are as follows: The size of the combustion space required appears to be directly proportional to the percentage of oxygen in the moisture-free and ash-free coal. The percentage of excess air that gives the best results varies with the size of the furnace and the kind of fuel. This fact explains why in one plant the highest efficiency may be obtained with 14 per cent of CO₂ in the gases and in another plant with only 10 per cent of CO₂. There is a definite relation for each coal between the excess air supply and the percentage of CO₂ in the furnace gases. Soot is formed at the surface of the fuel bed by heating the hydrocarbons in absence of air. It is not formed by the hydrocarbon gases striking the cooling surfaces of the boiler. As a matter of fact only a very small trace of the hydrocarbon gases ever reaches the surface of the boiler. Hydrocarbons that do so are prevented from decomposition by the cooling effect of the contact. The cooling surfaces do not cause the formation of soot they merely collect soot and prevent its combustion. It seems that most mechanical stokers are smokeless.

not because they burn the smoke, but because they burn the coal in such a way that very little soot or smoke is produced. Hand-fired furnaces are smoky because soot is produced in or near the fuel bed and cannot be burned in the limited combustion space of the furnace.—*Bulletin* 135, Bureau of Mines.

Traction

Connecticut Company's Power-Saving Campaign.—WILLIAM ARTHUR.—Systematic educational work has reduced the energy consumption per car-mile by 11 per cent in five months. The general details of the plans are given.—*Electric Railway Journal*, March 2, 1918.

Six-Motor Multiple-Unit Trains for Montreal.—KEITH McLEOD.—Details of a system of two-car semi-trail operation on grades up to 13 per cent. Among interesting features that are pointed out are the multiple-unit control with hand and automatic acceleration, semi-automatic brake system, emergency opening coupler and air-operated doors with safety interlocking control.—*Electric Railway Journal*, March 2, 1918.

Voltage Regulator and Phase-Balancer Regulator Equipment of Philadelphia Electric Company.—R. M. CAROTHERS.—The equipment described in this article was installed to distribute a heavy single-phase railway load over the three phases of the generators. The boosters with their independent exciters maintain constant voltage on the phase from which the railway load is taken, and a shunt phase converter distributes the load to the other two phases and maintains the voltages of these phases equal to that of the first. The single-phase railway load at times reaches the value of 24,000 kva., and the manner in which this load is smoothed out is shown by a chart from a recording voltmeter. Records from the indicating wattmeters and ammeters also show how satisfactorily the phase converter adjusts the load between the three phases.—*General Electric Review*, March, 1918.

Installations, Systems and Appliances

Voltage Regulation of Three-Phase Feeders by Automatically Controlled Induction Regulators.—M. UNGER.—This article treats of the voltage regulation of a three-phase feeder by one three-phase automatic induction regulator and by two or three single-phase automatic induction regulators. Three means are thoroughly discussed and the conclusion is drawn that two single-phase regulators will maintain a better regulation on a three-phase three-wire feeder, carrying mixed power and lighting load, than will a three-phase regulator. The cost, losses and efficiency of either method of regulation will be practically the same. In case it is desired to obtain the best possible regulation on all of the three phases a third single-phase regulator should be added.—*General Electric Review*, March, 1918.

Selection of Steel-Mill Auxiliary Motors.—J. D. WRIGHT.—The functions, mechanical layout and operation of blooming-mill manipulators are discussed. Conclusions are reached as to the size and type of motors as well as the type of control best suited for driving these auxiliaries.—*Proceedings A. I. E. E.*, March, 1918.

Economic Industrial Applications of Electricity.—NORMAN T. WILCOX.—Among the subjects discussed by the author in this paper are the following: Economic

uses of electric service, industrial and domestic service, economy of isolated plants, the electric vehicle, refrigeration, electrochemical applications, electric steel furnaces (basic and acid process) and furnaces for non-ferrous metals.—*Journal of the Western Society of Engineers*, October, 1917.

Wires, Wiring and Conduits

Current Capacity of Copper Busbars.—F. M. BILLHIMER.—Considering direct-current conductors, the author says that since the temperature rise of a conductor carrying a direct current depends upon the amount of surface exposed to the air and the resistance of the conductor, it is evident that a conductor large enough in cross-section to carry several thousand amperes with a given rise can be replaced by several small conductors with a total surface greater than that of the large conductor, but with a smaller total cross-section. Problems which are encountered in the application of conductors to direct-current circuits also apply to alternating-current circuits, but in addition to the limits which resistance, shape and spacing place upon the capacity of the direct-current conductor, skin effect and mutual induction must also be considered, as these factors cause non-uniform current distribution in the alternating-current conductor. For laminated-bar conductors arranged with vent ducts and carrying alternating currents the current distribution will, in general, be made as nearly uniform as possible by separating the conductors as far as practicable and making the thickness of the conductor a minimum. For mechanical reasons the thickness of individual bars cannot be reduced too far. In general, no exceptional mechanical difficulties should be encountered in handling currents of 2000 amp. or 3000 amp. For heavier currents careful consideration must be given to the design of both direct-current and alternating-current conductors. Tables and curves are presented giving the effect of spacing on the current-carrying capacity of direct-current copper conductors, variation of temperature with different bar spacings, effect of spacing on current-carrying capacity of conductors, etc.—*Electric Journal*, March, 1918.

Electrophysics and Magnetism

Edge Effect in Copper Bars at Electric Lighting Frequencies.—The results of experiments made to determine the extra resistance due to non-uniform current density in large copper bars carrying alternating currents at 60 and also at 25 cycles per second. Under the conditions which existed in the test, the ratio of the alternating-current resistance to the direct-current resistance is 1.1 to 1.3 at 25 and 60 cycles respectively. These results indicate that the edge effect in large copper bars is of considerable practical importance at ordinary lighting and power frequencies. The ratio of the alternating-current resistance to the direct-current resistance in circular copper bars having the same cross-section as the rectangular bars investigated was less than half that found in the latter. The largest resistance ratio found was 2.2 at 61 cycles in the case of a loop 4.9 m. long with its sides 5.1 cm. apart. Each side of this loop was composed of three copper bars in parallel, clamped in such a way that the individual bars were 6.35 m. apart.—*Journal of the Franklin Institute*, March, 1918.

Electron Discharge Apparatus.—Description of a new form of vacuum tube in which the filament consists in part of thorium, which at a given temperature has a much greater electron emission per unit surface than refractory metals such as tungsten. With this tube substantially the same electron emission per square centimeter has been obtained at a temperature of about 1300 deg. to 1380 deg. K. as with a pure tungsten filament at 2000 deg. K.—*Wireless Age*, January, 1918.

The Electrical Properties of Some High-Resistance Alloys.—M. A. HUNTER and F. M. SEBAST.—In this article the authors point out that high-resistance alloys must be sought for among those combinations in which metals are in solid solution in one another. An increase in the resistivity of an alloy is usually associated with a decrease in the temperature coefficient, although this is not always so. Ternary alloys have in general a higher resistivity than binary alloys of the same approximate composition. The highest resistivities in the binary alloys were found with nickel-manganese and nickel-chromium alloys. In ternary alloys the highest resistivities were met with ferro-nickel-manganese and ferro-nickel-chromium and copper-nickel-chromium. Chromium alloys withstand oxidation at high temperatures better than the corresponding manganese alloys. Wires of low temperature coefficient were found chiefly among the copper-nickel-manganese alloys. A series of alloys of copper-chromium are indicated which have relatively high conductivities and tensile strengths.—*Rennselaer Polytechnic Institute, Bulletin No. 10*.

Units, Measurements and Instruments

Characteristics of Current Transformers on Open Circuit.—W. R. WOODWARD.—By means of vector diagrams the author explains the operation of a current transformer under normal and open-circuit conditions. Curves are given showing typical current-transformer current and voltage waves with the corresponding flux wave and hysteresis loop for high-grade transformer steel. Reference is made to two methods of measuring the peak voltage on open circuit—one by the crest voltmeter and the other a modification of this method. It is pointed out that when the secondary is open the voltage will, in general, be increased with greater area of magnetic circuit, greater number of secondary turns or higher frequency. The converse is also true.—*Electric Journal*, February, 1918.

Telegraphy, Telephony and Signals

Telegraphic and Telephonic Progress in the United States.—A reprint from the *Annales des Postes, Télégraphes et Téléphones* of the general features of the report submitted by the engineers sent by the French government to examine into American methods and progress in the administration of the post office and in telegraphy and telephony. Results achieved in long-distance telephony, in radio-telegraphy and radio-telephony and in the use of multiplex printers in the reception of telegraphic messages are among the things commented on appreciatively by the visitors.—*Revue Générale de l'Electricité*, Feb. 2, 1918.

Telephone Exchange Transfers and Their Organization.—F. G. C. BALDWIN.—(Abstract of paper read before the Institution of Electrical Engineers.) After giving three ways of effecting telephonic exchange transfers, the author discusses the relative advantages

of each and outlines the problems involved in carrying out the various steps of the transfer. Methods of extracting the heat coils, withdrawing the fiber separators, providing testing and other facilities, changing all of the circuits by making T-connections and handling the exchange organization while the transfer is being made are discussed. The steps which can be taken to secure uniformity of attention to calls, to preclude interruption of service, etc., are outlined.—*London Electrical Review*, Feb. 22, 1918.

Telegraphy Through the Ground.—CHARLES NORDMANN.—A recent order of the German General von Galwitz contained instructions telling how the Germans are using a method of communication known as "telegraphy through the ground." In general, it is a method of communication which is a compromise between wireless telegraphy and one-wire telegraphy. One feature which the new method and the wireless method have in common is that two communicating stations are not connected by wire. They differ in that the wireless sends its waves through the air while the new method transmits them through the ground. These currents are nothing more than induction currents. A wire is placed along the fighting front with both ends extending into the ground, and current is produced in the circuit by some such means as a Rhumkorff coil. Installed similarly at some distance from this wire and parallel to it is another wire in which current is induced by the first, thus permitting the sending of signals from one station to another.—*Le Matin*, Jan. 18, 1918.

Miscellaneous

Horsepower Obtainable from French Rivers.—More than 9,000,000 hp. is obtainable from French rivers for 180 days in the year. Corresponding figures for other European countries show that France is especially favored in this respect, her water-power resources being considerably larger than those of Norway, Sweden or Italy, or, in fact, of any other country, except perhaps Russia, for which no statistics are given. It is also interesting to note that, although the German available water resources amount to only about 1,500,000 hp. per annum, she has utilized 31 per cent of them, whereas only 10 per cent of French water power is yet developed.—*Railway Electrical Engineer*, February, 1918.

Empirical Method for Determining the Ultimate from the Proximate Analysis of Coal.—J. P. CALDERWOOD.—Considered from the chemist's viewpoint, the empirical equations given in this article will not give accurate results, but they are suitable in connection with boiler testing. From an analysis of the possible errors involved, it is interesting to note that the largest error introduced is 1.4 per cent approximately, and that is produced in finding the theoretical air required per pound of coal. Another error which is introduced in calculating the terms of the heat balance amounts to about 8.5 B.t.u. Some relation between the hydrogen volatile matter, fixed carbon and heating value may be developed, the author says, which would add materially to the accuracy of the equations. In deriving the relation between the proximate and ultimate analysis of the coal, a theoretical formula was first established, found from observation or experimental values which contain the coefficients in a literal form.—*Pennsylvania State College Bulletin*, Vol. XI, No. 14, Nov. 15, 1917.

PROF. COMFORT A. ADAMS FOR NEXT A. I. E. E. PRESIDENT

He Is the Nominee of the Directors for Chief Executive of the Institute in the Year Beginning
Aug. 1, 1918

Prof. Comfort A. Adams of Harvard University and the Massachusetts Institute of Technology is the nominee of the directors of the American Institute of Electrical Engineers for president for the year beginning Aug. 1, 1918. This is substantially equivalent to his election.

The board has selected from the list of nominees its directors' ticket. Ballots, which will be sent to Institute members the latter part of this month, must be mailed, in order to be voted, to reach the office of the secretary, New York, not later than May 1.

COMFORT A. ADAMS

The list of directors' nominees to be elected at the annual meeting on May 17, 1918, is as follows:

For President—Comfort A. Adams, Cambridge, Mass.
For Vice-Presidents—William B. Jackson, Chicago; Harold Pender, Philadelphia; John B. Taylor, Schenectady; F. B. Jewett, New York; Allen H. Babcock, San Francisco; Raymond S. Kelsch, Montreal.
For Managers—Frank D. Newbury, Pittsburgh; G. Facioli, Pittsfield, Mass.; Walter I. Slichter, New York.
For Treasurer—George A. Hamilton, Elizabeth, N. J.

Comfort Avery Adams, the newly elected president of the American Institute of Electrical Engineers, was born at Cleveland, Ohio, in 1868. He was educated at the Case School of Applied Science, where he received

the B.S. degree in 1890 and the degree of E.E. in 1895.

Professor Adams assisted in physics prior to his graduation; he was engaged in engineering design in 1890 to 1891. In the latter year he became an instructor in engineering at Harvard University, being appointed assistant professor in 1896. Ten years later he became full professor, and since 1914 he has been Abbott and James Lawrence professor of engineering at Harvard and the Massachusetts Institute of Technology.

Professor Adams has been actively engaged in consulting engineering for the past sixteen years, among his clients being Stone & Webster, Boston; American Tool & Machine Company, Boston; Warner Sugar Refining Company, New York; Simplex Wire & Cable Company, Cambridge, Mass.; the Okonite Company, New York, and the Boston Edison company. He was a member of the international jury of awards (department of electricity) at the Louisiana Purchase Exposition, St. Louis, Mo., in 1904.

Besides being a member of the Engineers' Club of New York and other organizations of non-technical character, Professor Adams is a fellow of the American Academy of Arts and Sciences and of the American Institute of Electrical Engineers, having been chairman of the Boston branch in 1905 and 1906, and is secretary of the standards committee of the American Association for the Advancement of Science. Professor Adams also is a member of the Institution of Electrical Engineers, London; of the Illuminating Engineering Society, Society for the Promotion of Engineering Education, American Physical Society and National Electric Light Association.

He has contributed many scientific papers to the technical press and is the author of "Dynamo Design Schedules."

Professor Adams has a host of friends in the electrical profession, who have been drawn by his sterling worth as a man no less than by his scientific and engineering attainments. He has never lost touch with the practice of his profession, although much of his work has lain in the fields of theory and investigation, and his interest in so-called "practical" affairs has led him to contribute many valuable discussions to engineering society meetings.

National Contractors Now in New York

The National Association of Electrical Contractors and Dealers announces that since March 20, 1918, the organization headquarters have been at Room 1703, 110 West Fortieth Street, New York City.

This change, it is agreed, is to the best interests of the association and the industry in general, says Harry C. Brown, the secretary, in announcing the opening of the new headquarters.

Hearings on Administration Water-Power Bill

Congressional Committee in Receptive Mood, and the General Atmosphere Appears Favorable for Legislation Permitting Development Under Conditions Attractive to Private Capital

HEARINGS on the so-called "administration" water-power bill were held in Washington this week before the joint power committee of the House of Representatives which was recently created to pilot the measure through the House. The atmosphere which permeated the committee room was unlike that at other water-power hearings, and there were unmistakable signs that the committee appreciates the necessity of water-power development and is anxious to ascertain under just what conditions private capital can be induced to accept the financial burdens incident to such development.

While every effort is being made to safeguard the interests of the government and of the consuming public, the disposition is to be as liberal as possible in other details so that no injustice shall be done.

Government officials themselves have experienced a change of heart, and there has been no bitter attack on the "water-power trust" or grasping monopolies. In fact, some of the Congressmen have been at pains to draw out from witnesses whether there was such a thing as a "water-power trust" and seemingly were convinced from the answers that no such trust exists or has existed.

Now and then the chairman of the committee, Congressman Sims of Tennessee, put leading questions which might cause one to suspect that the government itself might engage in hydroelectric development if permitted to do so under the Constitution.

None of the witnesses who appeared up to Thursday morning had any serious objections to make to the measure as a whole, which they considered to be the best of its kind thus far offered, and the amendments and changes which they suggested had in view the elucidation of some of the minor features or a change to make the bill more attractive to private capital.

The position of the government with reference to the bill and to water-power development in general was outlined by O. C. Merrill of the Forestry Service, who appeared before the committee on Monday and Tuesday. H. J. Pierce of Seattle, Wash., Calvert Townley of the Westinghouse Electric & Manufacturing Company, New York, and E. K. Hall, vice-president of the Electric Bond & Share Company, were heard on Tuesday afternoon, and John A. Britton, vice-president and general manager of the Pacific Gas & Electric Company of San Francisco, took up all of Wednesday morning and a part of the afternoon discussing California conditions. H. T. Freeman of the Connecticut River Company of Hartford and H. J. Harris of the Big Horn Canyon Irrigation & Power Company of Hardin, Mont., were also heard on Wednesday afternoon, Mr. Harris resuming his testimony on Thursday morning.

POSITION OF THE GOVERNMENT

Speaking as the representative of the Secretary of War, the Secretary of Agriculture and the Secretary of the Interior, Mr. Merrill said:

"The shortage of fuel, the overloading of our transportation systems, the demands for industrial power and the unsatisfactory financial situation of our public utilities emphasize as never before the imperative need of immediate, adequate and comprehensive legislation. Our industrial efficiency, both during the war and thereafter, will be increased or diminished according to whether we do or do not make adequate provision for the development of our water-power resources. In view of these circumstances, it is submitted that water-power legislation should be considered a war emergency measure and as such should be taken up by Congress and passed at an early date."

As the background for this statement Mr. Merrill showed the rising cost of all structural material and how power-plant equipment likewise has gone soaring. Hydraulic machinery has advanced, he said, from 100 to 150 per cent over 1914 prices; electrical apparatus from 125 to 150 per cent; steam turbines, 150 per cent; water-tube boilers, 170 per cent, in addition to uncertainties in delivery. He showed the increasing scarcity of coal, fuel oil and labor and their consequent higher cost and what effect these have had and will have on power production, especially on the Pacific Coast.

These increased costs have resulted in increased cost of steam-power production and have made water-power development increasingly attractive. In fact, they have placed a considerable premium on water power, the utilization of which reduces the use of fuel and the drain on the fuel reserves. Water-power development is therefore a measure of economy as well as a measure of conservation.

INCREASING DEMAND FOR POWER

Notwithstanding increased costs of construction and of operation, the demand for power has increased not at a uniform but at an accelerating rate until during the past two years the annual increment in power generated by central stations alone has been from three to four billion kilowatt-hours, requiring an annual increase in installation of from one and a half to two million horsepower. From the close of 1914 great expansion has taken place, and in 1917 the output of 64 per cent of the industry was 61 per cent in excess of the output of 1914, which in turn was greater than that of any preceding year. Output figures for 1914, 1915, 1916 and 1917, computed from data published in the *ELECTRICAL WORLD*, were offered by Mr. Merrill.

It was Mr. Merrill's firm belief that the demand for power will continue to increase while war continues, in order to supply power to constantly expanding war industries, and when the war is over to provide for the extension of public utilities and of the electrochemical industries, for electrification of railroads, and for a multitude of other activities that will accompany the period of reconstruction. As for financing of public utilities, Mr. Merrill said, "The power industry must continue to expand or war preparations will be halted."

RELATION OF LEGISLATION TO EXISTING DEVELOPMENT

The situation, according to Mr. Merrill, shows the need of immediate action on the present measure. He said:

"Even if new water-power developments for the period of the war may be few or none, extension will be required to existing plants in order to meet constantly increasing power demands. If satisfactory legislation is passed, such extensions will be made, particularly in those sections of the country where the rising cost of fuel has become a serious factor in steam-plant operation. But even if new water-power developments could not be undertaken and extensions to existing developments could not be made, legislation will still be necessary in order to give such security to existing developments, hitherto made under unsatisfactory laws, that they may be able to meet their maturing obligations.

"Under the existing financial conditions, uncertainty of tenure places a serious handicap on corporations, making the refunding of obligations unduly expensive if not altogether impossible. Legislation which will permit of the financing of water-power developments upon favorable terms and legislation such as is contained in the 'War Finance Corporation' bill are imperatively needed if our public utilities in general and our water powers in particular are to be able to satisfy the unprecedented demands placed upon them and at the same time to meet their financial obligations.

"While it is essential that water-power legislation should protect fully the public interests in our national resources, it is equally essential that adequate protection should be given to the private capital by means of which such resources are developed. It is believed that the bill before you meets both requirements and that under its provisions capital can be secured and development will take place."

EXTENDING NAVIGATION ON THE COLUMBIA RIVER

Henry J. Pierce of the Washington Irrigation & Development Company told of the possibilities of the Columbia River at Priest Rapids in the central part of Washington. There, by means of a dam at the foot of the rapids and the expenditure of \$25,000,000, the river would be made navigable for a further distance of 200 miles; 250,000 hp. could be developed continuously and an additional 250,000 hp. during flood water, or a period of six months. In addition 500,000 acres of desert land would be brought under cultivation. He asked that a holder of a priority permit be protected in all expenditures made in good faith in the development of water power and that he be given the preference for a permit as against others who have not expended time or money. He also asked that any tax imposed should be on the actual power developed, and that in case the license is to be renewed the original licensee have the first right.

Mr. Townley's testimony did not differ essentially from his brief before the United States Chamber of Commerce, which was outlined in the *ELECTRICAL WORLD* of Jan. 26, 1918. His contention was that, no matter how favorable the legislation, no very great amount of hydroelectric development would be undertaken because of the competition with steam-turbine equipment and the cheapness with which a steam station could be built.

THE VIEWPOINT OF THE INVESTMENT BANKER

E. K. Hall of the Electric Bond & Share Company made an excellent presentation of the water-power situation from the viewpoint of the investment banker. He assumed that Congress would cast every safeguard about the water-power resources for the protection of the public. Having done that and provided for the recapture of the property at the end of fifty years as well as for the regulation of the rates and service by public service commissions, it should make it as attractive as possible to get the water powers developed.

He found two fundamental defects in the bill and suggested remedies for these. No other commercial enterprise, he maintained, called for so large an investment for the profit derived as did a water-power station. In commercial circles the usual turnover is four times a year, while in hydroelectric work the turnover is only once in seven years. Moreover, the amount of investment required is very large in proportion to the amount of the business done. The investment must therefore be protected and made as safe as possible, otherwise money would not be forthcoming. A hydroelectric station differs from a steam station in that if it is a failure it is good for nothing else, whereas a steam plant can be utilized for some other purpose.

He cited by contrast the case of investments in land, where the owner holds title forever, as compared with a heavy investment in a hydroelectric property, where the lease is short, fifty years, with no surety as to what will happen to the title after that except that the property may be taken over by the government for the net investment, or passed to some other lessee or to the original lessee for no specified time. He asked that in the latter case the bill be amended to give a new lease to the development for at least thirty years.

People who invest in bonds, he said, cannot afford to take chances on the principal. They are satisfied to take a smaller return in order to secure safety, therefore the bond should not carry any greater hazard than that inherent to the business. There should be nothing in the legislation that should lead to uncertainty. After the end of the fifty-year period the investor should be assured of a fair deal. The term "just compensation" in the recapture clause would carry conviction and be acceptable to investors. If possible, enterprise and efficiency on the part of the licensee should also be rewarded.

CONDITIONS ON THE PACIFIC COAST

Mr. Britton traced the history of hydroelectric developments on the Pacific Coast and showed to what extent the State of California was indebted to the public utility companies for its upbuilding. As indicative of the unsatisfactoriness of existing regulation relative to development on the public domain, he cited the case of one of his company's projects having a potential possibility of 200,000 hp., which has been built, so far as its reservoirs, canals, flumes, forebays, pipe lines and power houses are concerned, entirely upon land, aggregating 12,578 acres (more than 5000 hectares), owned in fee by the power company, with the single exception of 38.7 acres (15.65 hectares) of land overflowed by one of the reservoirs. These 38 acres have been placed in the forest reservation. It is land barren and bare of any vegetation, granite rocks rising above other granite rocks, upon which vegetation would be im-

possible, and yet because the flooding of this meager acreage by the backfilling of the water from the dam impinges upon the alleged forest reserve, the government demands that all parts of the project shall come under its control and domination and be subject to the provisions and permits heretofore quoted.

In another instance his company has a power project having a potential possibility of 250,000 hp., said Mr. Britton, in which less than 2 per cent of the entire land devoted to the project is upon government reservation. The project could be developed (but the power would be lessened some 10 per cent) by moving down the stream a few feet, and the project would then be entirely without the forest reservation. Patriotic duty would seem to impose upon the promoters of this project the utilization of the water to the fullest extent possible, yet these conditions of patriotic submission would result in cost charges and obligations that would render it impossible to finance the project under the conditions imposed by present rules and regulations.

Mr. Britton said that the demands made upon the power companies for quick developments, owing to the building up of the population of California by the creation of industries and by the reclamation of other lands, taxed the resources of the power companies to such an extent that they could not, either financially or physically, keep pace with the demand, because of the restrictive conditions recited. Steam plants, therefore, because of less first cost, were erected as auxiliaries to water-power plants, and cheap oil in the earlier days of power demands made it possible to install steam plants near the center of load and to carry the peak load economically, and by tying in with the hydroelectric system to insure continuity of service economically. The low price of unit installation of steam plants, as against the much greater price of hydroelectric, also made such a condition possible. Because of shortage of rainfall last winter the Pacific Gas & Electric Company, with the consent of the Fuel Administration, is installing a 20,000-kw. steam-turbine unit so as to insure service to war industries this fall.

The necessities for hydroelectric development in California, if propounded in the form of an inquiry,

could best be answered by the statement that there is an extreme necessity for the conservation of that which is limited and exhaustible and has certain superior uses, as has oil, and the providing of a substitute therefor which is perennial and inexhaustible, such as water.

The dependency of the State upon a water supply sufficient to operate its hydroelectric plants during the ordinarily dry season has been upon the stored water, not in reservoirs alone but as well in the frozen packed snow in the high ridges of the mountains that flank its eastern border. This frozen and packed snow slowly melts during the spring months, and the run-off is ordinarily amply sufficient to prevent draft on the reservoir storage until the months of June or July.

In the absence of this frozen snow and in the absence of additional reservoir capacity in the mountain regions, the supply of energy must be made up by steam plants. This situation now confronts California, the available storage being good for but forty-five days of demand, and it follows that steam must be resorted to for the other forty-five days of normal dry season to carry the load on the combined systems.

Encouragement of power projects by the government must be made by liberal terms, in order to insure the building of additional reservoir capacity to tide over abnormal years, such as this, and to minimize as much as possible the necessity for steam plants.

ANNUAL MEETING OF THE ASSOCIATED MANUFACTURERS

Large Advance Registration for Gathering on March
21 Indicated Successful Convention of Manufacturers in New York

A large advance registration indicated that the annual meeting of the Associated Manufacturers of Electrical Supplies at Delmonico's, New York, on March 21 would be attended by a great number of representatives of the companies.

The program, as outlined generally in previous issues of the *ELECTRICAL WORLD*, provided for a business session at 2 p. m. and a banquet at 7.30 p. m.

The Commonwealth Edison Company, Chicago, inserted in copies of its annual report to stockholders a reproduction of the company service flag, thus calling attention to the war activities of the many employees who are at the front.

LARGE BUSINESS OF THE WESTERN ELECTRIC COMPANY

Total Sales of More than \$150,000,000—Engineering Department Renders Important Service to the Nation in the War

Sales of the Western Electric Company, Inc., in 1917 were \$150,340,000, an increase of 40.5 per cent over 1916. This large total puts in concrete form the statement of President H. B. Thayer that "the business of the company has been larger than in any previous year. This is true of both the sale of its own manufactures and the sale of merchandise not made by it."

For 1916 the sales were \$106,987,000, and for 1915 they were \$63,852,000. The orders on hand Dec. 31, 1917, were \$1,950,000 in value less than on Dec. 31, 1916. The average value of an order filled during 1917 was \$107, as compared with \$75 for 1916.

Mr. Thayer says in the report to shareholders:

In our own manufactures the demands from regular customers (the Bell Telephone companies) were very heavy at the beginning of the year, but as the demands for equipment to meet emergency requirements directly or indirectly caused by the war have increased the ordinary requirements have decreased so that to a large extent a more expensive and less profitable business kept us busy during the latter part of the year. Therefore, while the profits in this class of business have been larger than in 1916, they have not, as compared with earlier years, been in proportion to the increased investment in the business. On sales of merchandise not made by us the profits have been very satisfactory.

There is no return from foreign investments included in the profits of the company for 1917. As to some information

is entirely lacking, and as to others it is incomplete. It is our belief, however, that as a whole a conservative valuation of them would require no addition to reserves, the earnings of some of them being apparently sufficient to offset the possible losses of others.

On the entry of this nation into the war we practically placed our engineering department at the service of the nation and believe that it has rendered important service. This has involved large expense and indirect loss through the interruption of our regular engineering program, but because we believed that we were able to render great service we believed also that the responsibility upon us to render it was great and that our stockholders would approve of our action. On such orders as we undertake for the military departments we have agreed to a basis of cost plus a very moderate profit.

The difference between present cost and cost on the basis of prices before the war on buildings and equipment added to the plant during the year has been credited to reserve for depreciation on plant.

It has seemed wise on account of the large merchandise investment and the prevailing high costs to set aside to the reserve for contingencies \$2,000,000 and on account of the large increase in the number of employees since the establishment of the employees' benefit fund there has been added to that fund the sum of \$500,000.

Our shop force increased during the year from 18,928 to 21,549 employees. The total number of employees at Dec. 31, 1917, was 30,737.

The total disbursements from the employees' benefit fund for 1917 amounted to \$173,915. These payments covered all classes of benefits and were made to 2894 beneficiaries.

Earnings for the year ended Dec. 31, 1917, follow:

Sales	\$150,340,359	
Other income	1,309,192	
		\$151,649,551
Cost of merchandise	\$135,427,053	
Expenses	8,487,527	
Taxes	1,073,411	
Appropriated for:		
Reserve for employees' benefit fund..	500,000	
Reserve for contingencies	2,000,000	147,487,991
Available for interest and dividends.....		\$4,161,560
Interest paid	\$1,309,844	
Dividends	2,550,000	
Carried to common stock.....	301,716	\$4,161,560

Real estate and buildings stand in the balance sheet at \$12,911,537 and machinery and equipment at \$12,134,759, a total of \$25,046,296. Total current assets of \$74,527,538 are divided as follows: Merchandise, \$44,415,028; cash, \$4,257,150; bills receivable, \$1,177,166, and accounts receivable, \$24,678,194. Sundry investments are \$13,094,686.

The 300,000 shares of preferred stock are listed at par, \$30,000,000. The common stock, 150,000 shares of no par value, is carried at \$25,755,364. There is also \$15,000,000 bonded debt, making total capital liabilities of \$70,755,364. Bills payable aggregate \$10,600,000 and accounts payable \$9,194,558. There are reserves of \$16,285,136 for depreciation on plant, of \$1,500,000 for employees' benefit fund and of \$4,333,462 for contingencies.

PACIFIC COAST SECTION OF N. E. L. A. POSTPONES MEETING

Convention Scheduled to Be Held at Del Monte on April 24 to 27 Is Postponed Indefinitely to Avoid Interference with Liberty Loan

Definite arrangements had been made by the Pacific Coast Section of the National Electric Light Association to hold a convention at Del Monte, Cal., on April 24 to 27, but to avoid interference with the campaign for the third Liberty loan it has been decided to postpone the meeting indefinitely.

ELECTRIC HOIST MAKERS FORM NEW ASSOCIATION

Services of Member Companies of Electric Hoist Manufacturers' Association Are Offered to Government to Facilitate War Service Work

The Electric Hoist Manufacturers' Association, by a resolution adopted at its last meeting, has offered the services of member companies to the government in meeting the extraordinary demand for their product.

The War Industries Board of the government has requested full information concerning the ability of the electric hoist manufacturers to handle the volume of business offered them, as well as regarding the effect of priority orders and embargoes on shipments upon the trade.

It is evident that the association will be of great assistance to the War Industries Board, as it is becoming more apparent from day to day that there are numerous advantages for all concerned in having manufacturers in certain lines organized. This is especially so now in the hour of national crisis. Instead of vindictive competition and antagonism along business lines the association brings the spirit of co-operation and exchange of ideas, looking toward increased output.

Electric hoists for shop use and handling material have gone through various stages of development during the last fifteen years and, like all other classes of shop machines, they cannot be successfully designed on the basis of theory alone. Actual experience in meeting hoist requirements and innumerable corrections and refinements in design on the part of the manufacturers have marked the progress of these last fifteen years in this important field.

The many mistakes on the part of both manufacturer and user during this development period have created in some instances a lack of confidence in electric hoists as a class. On the other hand, many users have been led to believe that such hoists are unaffected by abuse and can consistently be called "fool-proof."

Some discredit to these machines has developed on account of lack of standardization in nomenclature, service rating and general characteristics on the part of the makers.

Now that it is thought that the experimental stage has well passed and acceptable designs have been developed by various manufacturers, it appeared wise to co-ordinate the total experience and to make available for the user all that is best in electric hoist design and practice. With this object in view the manufacturers of the United States organized the Electric Hoist Manufacturers' Association, comprising the following companies: The Brown Hoisting Machinery Company, Detroit Hoist & Machine Company, Euclid Crane & Hoist Company, Franklin-Moore Company, Link-Belt Company, Roeper Crane & Hoist Works, Shepard Electric Crane & Hoist Company, Sprague Electric Works and Yale & Towne Manufacturing Company.

The officers of the association are as follows: F. A. Hatch, chairman, Shepard Electric Crane & Hoist Company; F. W. Hall, vice-chairman, Sprague Electric Works; C. W. Beaver, secretary-treasurer, Yale & Towne Manufacturing Company.

The association holds monthly meetings for the purpose of studying the specific needs of the hoist user and to develop standardized methods of presenting informa-

tion to him so that guess work will be eliminated. The association will consider uniform nomenclature pertaining to types and parts of electric hoists, fix upon a standard by which hoist motors shall be rated and promote the standardization of electric hoists as far as possible. It will also collect and disseminate information and statistics relative to the electric hoist industry, provide facilities and opportunities for study and education in regard to the economics of the industry, extend the use of the product by pointing out the great number of material-handling problems of different classes that can be solved by the use of electric hoists, promote friendly intercourse and co-operation among the members and disseminate information that long experience has taught is essential to any hoist to insure good results, and recommend to the members of the association well-established principles as to both construction and equipment that will tend to eliminate any possibility of inferior equipment.

The membership of the association is confined to those engaged in the manufacture of monorail electric hoists, which have revolutionized the handling and transportation of material in and about industrial plants.

SIGNAL CORPS HAS OPENING FOR MANY ELECTRICAL MEN

They Are Required for Various Branches of Important Army Radio-Communication Work of Several Classes

The Signal Corps, United States Army, has announced that it can use the services of a large number of men having electrical training. They are needed especially in connection with the radio-communication systems in use in the military service. All classes of electrical men—wiremen, expert electricians, storage-battery men, telegraph and wireless operators and men with electrical engineering training and experience—are wanted. The opportunity offered is unusual because of the great interest and importance of this branch of the service, which has been most aptly characterized as the nerve system of the army. Men engaged in the radio division of the communication work in particular have an increasingly important part in the great intelligence system upon which army operations are almost totally dependent.

The scope of this work requires men who will fall in general into three classes, depending on the character and amount of experience had by the individual; namely, radio operators, radio mechanics and field radio experts.

Application blanks for service in the radio work of the Signal Corps may be secured by addressing the office of the Chief Signal Officer, Land Division, Training Section, Washington, D. C. Men of draft age may make application and if qualified will be inducted into the army, at their request, for service in this branch of the Signal Corps.

After enlistment or induction, all personnel will be sent to one of several radio schools for six weeks to three months of intensive training in that one of the three general branches of the radio work for which their previous experience qualifies them. Some of the personnel completing these courses will be commissioned, advancement depending on individual ability.

DUTY OF THE COMMISSIONS IS CLEAR

BY MAX THELEN

President California Railroad Commission

In the situation which now confronts many of our public utilities the duty of the State commissions is clear. While providing for the continuation of adequate service, it is their duty to act promptly and vigorously on applications for increased rates based on increased operating costs.

Where the usual methods of rate making would result in unreasonable delays, short cuts must be applied to meet the emergency conditions.

Our public utilities must be kept in a sound and healthy financial condition, so that they will be able to meet not merely the requirements of their existing patrons but also the additional requirements of the war.

The State commissions should not wait until the utilities come to them with their pleas for assistance. It is their duty to inform themselves by their own investigations, if necessary, concerning the condition of the public utilities under their jurisdiction and to keep themselves constantly informed.

If the State commissions rise to meet the situation, as they are doing in all sections of the country, they will be rendering a substantial service not merely to the utilities and their patrons but also to the nation itself, which is largely dependent for war efficiency on the service of public utilities.

WAR-TIME PROBLEMS OF THE UTILITIES IN CALIFORNIA

President Thelen of the State Commission Shows How That Body Looks Upon the Conditions Created by the War

Max Thelen, president Railroad Commission of California, gave a lecture in the University of California extension public utility regulation course on March 6, at the Fairmont Hotel, San Francisco. His subject was "War-Time Public Utility Problems." President Thelen dealt with such utilities as street railroads, gas companies, electric companies and water corporations. He spoke of rates, services, extensions, and particularly finances. He set forth the problems and what is being done toward their solution. This lecture was open and free to the public.

Mr. Thelen divided his problems into four headings—rate, service, extension and financial problems. On rates he showed the difficulties of utilities in confronting the increased cost of operation, due to higher cost of fuel, materials and labor, the price of almost all materials having practically doubled. He said in part:

In California 106 formal applications have been made to the commission for authority to increase rates between April 1, 1917, the day on which war was declared to exist, and March 1 last, by such utilities as water, gas, warehouse, steamship, electric, railroad, telephone, jitney and express companies. These applications have ranged from requests for slight increases in small communities to applications of widespread interest and importance affecting all or large portions of the State, such as the applications of the Pacific Gas & Electric Company and the Great Western Power Company for authority to increase electric rates in the entire territory served by them in the central and northern sections of the State.

Forty-seven applications have been granted, sixteen have been denied or dismissed and forty-three are now pending. The commission realizes that the public utilities are suffering. Where an emergency exists and where the

usual method of handling rate applications, including a valuation of the property and an audit of the books, fails to meet the situation, the commission does not hesitate to apply emergency measures. We fully agree with President Wilson's letter to Secretary of the Treasury McAdoo that it is essential that these utilities be maintained at their maximum efficiency during the war, and that everything reasonably possible should be done to accomplish this end, and we act on that view. Public utilities should not expect to increase their profits during the war.

When a street railroad or other public utility comes before a State commission and asks for increases, it should come prepared to show that it has eliminated all unnecessary expense and has introduced all economies of operation compatible with the continuation of reasonably good service to its patrons.

Electric companies and their patrons in various sections of the country have already felt the effect of the so-called "lightless nights." These and other service problems must be solved, not on the basis of pre-war conditions, but from the point of view primarily of assisting to meet the nation's war requirements.

The necessity of conserving man power, materials and money necessarily has an important influence on the extensions of public utility systems during the war. Capital expenditures which before the war would have been entirely justified from the point of view of a particular utility and its patrons may now be inadvisable and undesirable because the utility may be able to get along for awhile without them, or because they do not harmonize with the unified operation of the particular utility concerned and other like public utility systems, all laying aside their purely competitive activities during the war. On the other hand, the requirements for additional light, heat, power and transportation by industries engaged in the production of necessary materials, supplies and food are such as to require imperatively all over the United States additions and extensions to the existing production and distributing systems of public utilities to meet the added requirements. It is essential that the financial strength and stability of these utilities be conserved by deferring capital expenditures not directly needed for war purposes, and that the funds thus conserved and such other funds as may be necessary be used for such additions and betterments as will assist most effectively to meet the nation's war requirements.

Soon after the outbreak of the war it became almost impossible for public utilities to secure large amounts of additional funds by the sale of securities in New York, Chicago and other financial centers of the country, with the exception of the sale of short-term notes, well secured and, in a few cases, of gilt-edge bonds at 6 per cent. The requirements of these utilities must be met.

Thus, in California, the commission during the eleven months beginning April 6 last authorized the issue by public utilities of \$72,828,150 stocks or bonds, as contrasted with \$99,625,000 during the twelve months ended June 30, 1917, and \$231,644,870 during the twelve months ended June 30, 1916.

The government has taken steps to provide that large issues of securities of public utilities and other concerns, both public and private, shall not be sold during the war in competition with government issues, and in no event unless really essential to the interests of the nation at this time.

Coal Production Better

Bituminous coal production, as reported by the United States Geological Survey, is now running ahead of last year's output.

HEAVY COSTS FOR POWER PRODUCTION

W. C. Slade, Telling Experiences of Rhode Island Company, Shows Great Need of Considering Boiler-Room Expense and Practices

Walter C. Slade, superintendent of power and lines of the Rhode Island Company, Providence, addressed the New England Street Railway Club at Boston recently on the difficulties and trials of producing steam-generated energy in war times.

"The question of the cost of production, although always of prime importance," said Mr. Slade, "has at times been obscured at least temporarily by the more important question whether for certain periods power could be produced at all, irrespective of the cost. In Rhode Island we have felt the shortage of bituminous coal keenly. The two power-producing utilities at Providence have been operating of late with inadequate coal reserves, and the Rhode Island Company in particular has recently been forced to operate its main power station for three or four days with borrowed coal entirely." Mr. Slade continued in part:

The prices which we have been forced to pay for coal in cargo lots alongside the Providence plant have varied, but they seem to be constantly increasing. In the spring of 1917 we paid as high as \$11 and \$12 a ton for some coal and bought considerable coal at prices between \$6 and \$9 a gross ton. Later developments proved that this action was justified.

The effect of the quality of the coal was reflected directly in the cost of operation, in addition to the effect of the higher cost of the coal alongside. It resulted also in increased boiler-room maintenance. The net result was to raise the unit cost of power for the year 1917 by 104 per cent, as compared with the twelve months ended June 30, 1916.

Between the average large 60-cycle central station and the average large 25-cycle railway station there can be no interchange of power except through frequency changers, a method which is sufficiently uneconomical to make this exchange feasible only for emergency purposes. Such an arrangement for emergency operation is, however, feasible.

It is also equally practicable in certain cases, it would seem, when new equipment is added to existing 25-cycle power plants, to install the equipment for 60-cycle operation, so that in the future more railway plants would be able to take advantage of central-station power, which in normal times is steadily being produced at decreasing cost, as well as of hydroelectric 60-cycle developments that will, doubtless, be made throughout the country.

But what of the small engine-driven railway plant that is struggling along trying to produce power cheaply even in normal times? Many of these plants could and should be shut down as soon as arrangements can be made for equipment suitable for operating from central station or hydroelectric service. With increasing cost of coal, the balance is all in favor of the big station, and it is questionable if the price of coal in future years will reach a minimum that is \$1 to \$1.50 a ton above the prices that prevailed before the war.

As regards increasing economies in our power stations I am going to speak principally of the boiler room. In ordinary times the fuel item will represent from 70 per cent to 75 per cent of the total cost of generated power. I recently stated that our own experience had seen the fuel cost reach a point equal to 83 per cent of the total cost; in fact, at least 90 per cent of the total cost was expended in the boiler room for fuel, water, wages, supplies and materials required for maintenance. We should indeed consider spending money in such a field where such a large proportion of the expense of production lies.

The best solution, perhaps, is to follow the practice, already observed I believe in a few cases, to put under the chief engineer a technically trained man or at least a man who understands the theory of combustion sufficiently well,

who can keep constant check of operating conditions in the boiler room, working in constant touch with the chief engineer. This type of man has been termed "combustion engineer."

Working with the assistance of the necessary weighing measuring and metering devices with which he should be provided, he could put the true spirit of industrial control into boiler-room practice. To aid the "combustion engineer," so called, in effecting the desired economies, it would be well to consider the advisability of making the operation of all equipment as nearly automatic as possible.

WORK ON FUEL ECONOMY BY NEW YORK COMMISSION

Conference in Albany Decides to Appoint Coal-Saving Committee if State Fuel Administrator Approves the Plan

How to effect economy in fuel and power consumption was the subject of a conference held on March 6 in Albany by the New York Public Service Commission, Second District, acting in co-operation with A. H. Wiggin, the New York Fuel Administrator. Chairman Hill of the Public Service Commission presided, and the Empire State Gas & Electric Association, which represents 90 per cent of the output of gas and electric light for commercial and street-lighting purposes, was represented by J. T. Hutchings of Rochester, C. A. Graves, C. H. B. Chapin and Stuart Wilder of New York and H. W. Peck of Schenectady.

The conference decided that, if the State Fuel Administrator approves the plan, a committee will be appointed to consider the possibilities of coal saving. The committee will consist of representatives of the State Fuel Administrator, the New York State Conference of Mayors, the Public Service Commission, Second District; two or three representatives of the gas and electric producers and the New York State Manufacturers' Association.

The plan, as outlined, provides for an educational campaign to effect economy in lighting and cooking and curtailment of non-essentials, including signs; economy in street lighting and in the operation of power plants and through saving of coal by concentration of generation; the utilization of water power through interconnection of systems and the development of unutilized water power.

DAYLIGHT SAVING HOUR WILL BE PUT IN FORCE

Effective from March 31 to Oct. 27, Central-Station Industry Is Studying the Possible Effect on Revenue and Output

President Wilson signed without ceremony the daylight saving bill on March 19. The effect of it will be that all clocks will be put forward one hour on the last Sunday in March and turned back again on the last Sunday in October. The official change in time will take place at 2 a. m. on the days mentioned.

The daylight-saving law is recognized in the electrical industry as primarily a war measure and is, of course, accepted patriotically as a necessary step in conservation. It is expected that the resulting curtailment in lighting will have some effect on revenues and the operation of the law is awaited with much interest.

Current News and Notes

Timely items on electrical happenings throughout the world, together with brief notes of general interest.

Patent Office Improvements.—A composite committee has been created by the National Research Council to make a preliminary study of the problems of the United States Patent Office and its service to science and the useful arts. This committee comprises L. H. Baekeland, W. F. Durand, Thomas Ewing, Frederick P. Fish, Robert A. Millikan, E. J. Prindle, Michael I. Pupin and S. W. Stratton. All interested in making any patent-reform suggestions are advised to forward them at once to Dr. W. F. Durand, National Research Council, Washington, D. C. The particular point upon which suggestions are desired is the manner in which greater efficiency and work of higher quality can be secured in the Patent Office.

Financial Extensions in War Time.—The Mount Whitney Power & Electric Company, Visalia, Cal., has filed with the California Railroad Commission an application for approval of a plan for financing the construction of necessary extensions to its system during the war. The company distributes electric energy in Tulare, Kern and Kings Counties and has estimated that it will have to expend during 1918 \$108,561 upon its system, besides \$216,936 for extensions. It will have available for the latter purpose only \$60,000 and has therefore devised a plan under the terms of which those making application for power will be required to advance to the company part of the cost of building the necessary lines. The plan further provides that ordinarily the company will not accept applications for power where they do not yield an income the first year equal to 20 per cent of the total cost of installation.

Rate Increase Sought in California.—The San Joaquin Light & Power Corporation has filed with the California Railroad Commission an application for authority to increase electric rates in Mariposa, Madera, Merced, Fresno, Tulare, Kings and Kern Counties. The application says that heretofore, under normal conditions of rainfall, the company has been able to generate almost all its energy at its hydroelectric plants, but that owing to the failure of rain this year in the San Joaquin valley, the lack of snow in the mountains and the consequent shortage of water for irrigation by gravity flow, even if there should be a normal rainfall for the remainder of the season, the company's hydroelectric plants could generate less than half of the required power for its consumers. It will therefore be necessary to operate steam plants and generate electricity by the

use of gas and oil as fuel, adding \$600,000 to the company's annual operating expenses, besides increased cost of materials, the larger sum paid in wages and higher taxes.

The Government Rebuffs the Sanitary District.—In one of the various controversies between the federal War Department and the Sanitary District of Chicago a special board appointed by the Secretary of War made the following statement as a part of its report: "To restore the diminished levels in the lakes by constructing contracting works in their outlets does not, however, present any series difficulties. Compensation for the loss of elevation on Lakes Michigan, Huron and Erie and their connecting rivers, due to an assumed diversion from Lake Michigan of 10,000 second-feet, will by the plan above outlined involve an expenditure of \$475,000. It is the opinion of the board that, while other plans have been proposed, compensation by fixed contraction works similar in general to those above described affords the cheapest and most satisfactory method of preserving the levels of the Great Lakes." Subsequent to this report the Sanitary District, in order to remove the continuous government objection to the withdrawal of water from Lake Michigan, offered to build and maintain the contracting works. On Feb. 26, 1918, the engineering bureau at Washington, through Chief of Engineers Black, reported adversely on the Sanitary District's proposal, finding that the bill for permitting the construction of the contracting work was in violation of a treaty with Great Britain.

Extension of Activities by Wisconsin Operators.—The Wisconsin Security Company, the main activities of which were formerly the financing and operation of Wisconsin public utilities, has increased its capital stock from \$300,000 to \$1,300,000 in the last year. During that time the company acquired the entire capital stock of the Manitowoc & Northern Traction Company. It also acquired the Calumet Service Company, furnishing Chilton, Wis., with light and power, as well as control of the Baltimore (Md.) Dry Dock & Shipbuilding Company. The latter is now the largest property controlled by the company. It is said that with its new addition this property represents an actual physical value of more than \$7,000,000. On the property of this company eight ships of 8800 tons are now being built for the Emergency Fleet Corporation, according to Clement C. Smith, president of the Wisconsin Security Company. The company is also building ten 6200-ton steel cargo ships under contract for the Cunard Steamship Company, the French Republic and Norwegian and British owners. These have been commandeered by the Emergency Fleet Corporation. The company is building seven ships for the Navy Department. In his report Clement C. Smith said: "This shipbuilding activity is a big feature of our 1918 business. Our Wisconsin enterprises will be held in obedience until a more favorable time."

Associations and Societies

A complete Directory of Electrical Associations is printed in the first issue of each month on the next-to-last text page.

Providence Engineering Society.—"Motor Troubles" were discussed by W. F. Hodges of the J. H. Electric Company before the Providence Engineering Society on March 13.

N. E. L. A., Brooklyn Section.—W. Uckele presented a paper on "Pressure Regulation on Two-Phase, Sixty-Cycle Feeders" before the Brooklyn company section of the N. E. L. A. on Feb. 19.

Engineers' Society of Milwaukee.—Prof. C. M. Jansky, assistant professor of electrical engineering, University of Wisconsin, gave a talk entitled "Science in War" before the Engineers' Society of Milwaukee, March 13, 1918.

A. S. M. E., Philadelphia Section.—A paper on "Recent Developments in Methods of Measurement" was presented by Dr. F. W. Stratton of the United States Bureau of Standards on March 26 before the Philadelphia Section of the American Society of Mechanical Engineers.

Columbus Electrical Contractors' Association.—At the annual meeting of the Columbus (Ohio) Electrical Contractors' Association on March 14 Carl Entekin was chosen president, William McGarait vice-president and Charles Weisz secretary-treasurer. The members reported business conditions good.

Engineering Society of Buffalo.—"Hydroelectric Power Problems" was the title of a paper by J. A. Johnson presented before the Engineering Society of Buffalo on March 13, 1918. In this paper the author discussed the general considerations involved in the location of industries for economic reasons.

New York Electrical Society.—"Experiences at the Front in France and Flanders" was the title of a talk at a joint meeting of the Engineers' Club and the New York Electrical Society by Lieut. Pierre Chevalier, Twenty-second French-Canadian Battalion, on March 18, 1918. Dr. Charles A. Eaton, head of the National Service Section of the United States Shipping Board, Emergency Fleet Corporation, also spoke on "The United States as a Test of Democracy."

Spring Meeting of the A. S. M. E.—General war subjects and a discussion of how the engineer can help the government in the war will be the important features of the spring meeting of the American Society of Mechanical Engineers in Worcester, Mass., June 4 to 7. The meeting will open on Wednesday, June 5, which will be New England Day, and the discussion will dwell on the interests of New England in relation to the war. The remainder of the time will be spent in general and technical sessions and inspection trips.

Recent Court Decisions

Findings of higher courts in legal cases involving electric light, power and other public utility companies.

Implied Repeal of City Charter.—A municipal corporation whose charter as amended in 1901 gave it general authority to take water from any brook in a named town instituted condemnation proceedings for the purpose of increasing its water supply by taking the waters from a tributary to a creek in which the defendant corporation proposed to erect a power plant and had erected dams, etc. The respondent corporation, chartered in 1905, was authorized to build dams on the creek and its tributary for the purpose of providing necessary ponds and reservoirs to utilize the power of the stream, and in that connection was granted the powers of individuals to flow lands. The respondent corporation was also authorized to generate electricity and distribute it, and further to construct a railroad, etc. The Supreme Court of Errors held, in *East Hartford Fire District versus Glastonbury Power Company* (102 A. 592), that, as it only received the flowage rights of individuals, and the flowage act does not authorize the condemnation of land except for raceways, respondent's authority to build dams was necessarily to be exercised on lands acquired by consent of the grantors and lessors, and hence its charter was not an implied repeal of the authority of the municipality to take water to increase its water supply.

Property Devoted to Public Use in Eminent Domain Proceedings.—As virtually all streams available for municipal water supply were at an early date utilized for water power either directly or through their connecting waters, statutes generally authorizing municipal corporations to acquire waters for municipal water supply must be deemed operative upon streams already used for water power, at least when such water power is not already employed in some other public use at the time of the proposed taking, the Supreme Court of Errors of Connecticut held in *East Hartford Fire District versus Glastonbury Power Company* (102 A. 592). Property already appropriated to one public use cannot thereafter be condemned for an inconsistent public use unless such taking is authorized expressly or by clear implication, and this rule applies to property about to be lawfully appropriated to a public use, though the appropriation is not complete. Where respondent corporation authorized to exercise the flowage rights of individuals and use water of a creek to generate electricity had not commenced the generation and distribution of electricity, although it had acquired rights in the stream for that

purpose, such corporation cannot, its property not being devoted or about to be appropriated to a public use, defeat condemnation by municipal corporation which sought to take the waters of a tributary stream to increase its water supply.

Failure to Remedy Defect in Abandoned Charged Line.—A power company that left a branch wire across a pasture connected and charged after abandoning its use had no right to presume that the wire would continue to remain in a proper and reasonably safe condition without being looked after, the Kansas City Court of Appeals held in *Kribs versus the Jefferson City Light, Heat & Power Company* (199 S. W. 261). Where an unused branch power line was left highly charged in a place where persons frequently went it was the duty of the power company to see that the line was maintained in a reasonably safe condition, and if it got into a dangerous condition and remained so for such a length of time that the power company in reasonable prudence should have discovered and remedied the defect before an accident, it was negligent. That boys, one of whom was killed when he grasped a guy wire dangling from a charged power wire, were in the pasture without authority from the owners could not excuse the power company from liability for its negligence, persons having frequently passed through the pasture for so many years that it was incumbent on the company to keep its line safe and that it incurred legal liability because of any failure to do so.

Date and Point of Shipment Determine Classification of Goods Shipped.—The Gibbes Machinery Company had a fire in its storehouse in which a lot of gasoline engines were badly damaged. All the small parts of the engines, including trimmings, etc., were either melted or broken off, and for the purpose of having them rebuilt, if it could be done profitably, they were sent to the factory where originally made. The machinery company offered to ship them as scrap iron, but the carrier refused, and they were shipped as "burned engines," and the rate for that class was charged. Upon their examination at the factory it was found that the cost of rebuilding the engines would be more than new engines were worth, and they were therefore sold as scrap iron by direction of the machinery company, whereupon the latter demanded of the carrier the difference between the rate paid and that which would have been paid if the shipment had been classed as scrap iron. The Supreme Court of South Carolina, holding the shipper not entitled to recover (93 S. E. 718), said: "The justice of the case as well as the law is with defendant. Plaintiff had no right to require defendant to assume or bear any part of the expense incident to its experiment. Under the act of Congress, the classification of the shipment was to be determined at date and point of shipment, and charges made and collected according to the schedules and tariffs filed with the commission."

Commission Rulings

Important decisions of various state bodies involving or affecting electric light and power utilities.

Property Values Under War Conditions.—The decision of the New York Public Service Commission, First District, reducing electric rates of the Flatbush Gas Company says, in speaking of value: "It is contended by the respondent that it is entitled to a fair return upon the amount of property used by it in the public service, measured by opinion estimates of the reproduction cost thereof, even where data of actual cost are available. The claim that its return should be calculated on estimates of what it ought to cost to reproduce the property is moderated slightly by its obviously proper concession that there should first be deducted from the face of these estimates the amount of the accrued depreciation, figured, not on the reproduction cost new of the property, but upon the much lesser amount of original cost, and also that the unit prices to be assumed or assigned for the reproducing of the property should be taken from or reduced to pre-war and normal market levels. If, however, it is to be recognized that the value of the property upon which the respondent is entitled to earn a return through its rates is to be measured solely by the reproduction cost thereof, unaffected by consideration of the actual outlay therefor by the investors and regardless of the methods and conditions of original construction, then logically there would seem to be no escape from the conclusion that the respondent would be entitled to claim a return upon such a property cost as would be attributable to it if all the property were produced or reproduced in one continuous operation at present-day market prices of labor and materials. In the present juncture of universal upheaval, the application of such a postulate of evaluation to rate making would lead to startling consequences. Without a dollar of additional investment and in the face of adversity and suffering, the value of the respondents' property would be deemed to have vastly increased, and the amount which the company's investors are entitled to take from the consumers would be deemed to have much increased. On restoration of normal conditions investment made in property of the company at war-time market prices will of course shrink in value, perhaps violently, as prices tend to resume normal levels, and even the investments previously made might shrink if there should be a considerable depression in market quotations." The dangers of computing return on estimates of reproduction cost less depreciation were never so obvious as to-day, the commission holds.

K. E. N. Cole has been appointed manager of the Van Buren branch of the Fort Smith (Ark.) Light & Traction Company.

M. L. Hibbard, manager of the Union Light, Heat & Power Company, Fargo, N. D., was elected president of the Associated Charities of Fargo for the year 1918.

D. T. Laylin, formerly in charge of the electrical department of Strong, Carlysle & Hammond, has been appointed electrical engineer for the Standard Parts Company of Cleveland.

Herbert J. Baker, who has been a manufacturers' agent for electrical equipment at Denver, Col., is now electrical and mechanical engineer for the Evergreen Mines Company at Apex, Col.

Harry A. Porter, president of Harry A. Porter, Inc., Chicago, and vice-president of the Chicago Club-Jovian League, has been elected chairman of the electrical subdivision of the Chicago Association of Commerce.

Frederick W. Johnson, advertising manager for the Puget Sound Traction, Light & Power Company, formerly at Bellingham, Wash., has been appointed assistant to E. C. Macy, in charge of all construction for the Stone & Webster Corporation in the Northwest, with general headquarters in Seattle. Mr. Johnson has been in the employ of the Puget Sound company since July, 1906, in various capacities.

Roy B. Woolley, now in the publicity and sales department of the Society for Electrical Development, has been appointed director of publicity of the society to succeed Harry W. Alexander, resigned. Mr. Woolley was formerly sales manager for the Standard Electric Stove Company, Toledo, and at one time associated with the MacManus-Kelley Company, Toledo, and the F. Bissell Company, Toledo.

Dr. F. G. Keyes, formerly chief engineer of the Cooper Hewitt Electric Company, Hoboken, N. J., has received the commission of captain in the chemical section of the National Army. Dr. Keyes severed his connection with the Cooper Hewitt company late in 1916 to take charge of physical chemistry at the Massachusetts Institute of Technology, although he was still engaged by the company in a consulting capacity.

Harry W. Alexander, director of publicity for the Society for Electrical Development, New York, has resigned to become assistant to the president on sales, American Writing Paper Company, New York and Holyoke, Mass. It was Mr. Alexander who as publicity manager of the society organized and successfully directed the work of the local committees and the publicity and sales work of both the "Electrical Prosperity Week" (1915) and "America's Electrical Week" (1916) campaigns. Prior to joining the staff of the society in 1914 he was sales manager of the Federal Light & Traction Company, having earlier been a financial and political writer in Chicago.

Men of the Industry

Changes in Personnel
and Position—
Biographical Notes

W. R. Putnam, district manager of the Utah Power & Light Company, has been made a director of the Utah Manufacturers' Association.

T. R. Steingoetter has been appointed manager of the Edwardsville (Ill.) office of the St. Louis County Gas & Electric Company. He has been serving this company as a traveling auditor and more recently as general auditor in East St. Louis. He began with this company as messenger boy in the Belleville (Ill.) office.

Prof. George F. Sever, formerly professor of electrical engineering and acting dean of the faculty of applied science at Columbia University and for over twelve years consulting electrical engineer for the department of water supply, gas and electricity in the city of New York, has been commissioned a major in the Engineer Officers' Reserve Corps, with headquarters in Washington, D. C. He has closed his engineering office in New York. Professor Sever first entered the teaching profession as instructor in the electrical engineering department of Columbia University after fifteen years of commercial experience, largely with the Thomson-Houston Electric Company. In 1900 he was promoted to be adjunct professor of electrical engineering, and five years later he became professor. He was a member of the commission appointed by Mayor McClellan to draw plans for a municipal lighting system for Greater New York. Professor Sever is the author of a number of books connected with the subject of electrical engineering.

Obituary

John P. Sparrow, chief engineer of the New York Edison plants, died on Monday at his home in Brooklyn, at the age of fifty-eight years.

Charles H. Williams, well known as a public utility operator, died in Denver, Col., on March 10 of pneumonia. Mr. Williams, who was forty-four years of age and a graduate of the University of Wisconsin in the class of 1896, was one of the first college engineers to work for Henry L. Doherty. This was with the Madison Gas & Electric Company in 1897. Subsequently he became general superintendent of that company, and in 1905 he was made manager of the Wisconsin Light & Power Company at La Crosse, Wis. Then he went west with the Northern Colorado Power Company. For the last half dozen years Mr. Williams has been engaged in building and operating gas and electric plants in the West.

Austin C. Dunham, who for many years was president of the Hartford (Conn.) Electric Light Company, during which time he was one of the recognized leaders in the central-station industry, died on Monday at St. Petersburg, Fla., at the age of eighty-five. Mr. Dunham retired from the presidency of the Hartford company in 1912 after a period of service extending over thirty years. During that time the Hartford Electric Light Company was constantly in the forefront in central-station advance and achievement. Because of Mr. Dunham's foresight and deep-founded faith in the future of the electric lighting industry, the Hartford company has the distinction of being the first to adopt modern methods of transmission of energy from water power, the first to use polyphase transmission apparatus and to introduce extensively alternating-current inclosed-arc lamps, 60-cycle rotary converters and the constant-current alternating arc-light system. It was also Mr. Dunham who led the way to the adoption of the steam turbo-generator as a part

A. C. DUNHAM

of regular central-station equipment and who besides launched the Nernst lamp into commercial being. In addition to these, the first storage battery used in connection with central-station service was installed at Hartford, as were also the first tungsten street lamps. In such manner did Mr. Dunham set the pace for the central-station industry. Mr. Dunham was born on June 10, 1833, in Coventry, and was graduated from Yale College in 1854. In addition to the central-station field, Mr. Dunham had been in the forefront in other industries, having been president of the Dunham Hosiery Company and the Rock Manufacturing Company, one of the founders of the Austin Organ Company and the Automatic Refrigerator Company, a director of the Aetna Insurance Company, the Travelers' Insurance Company, the National Exchange Bank of Hartford and the Cedar Hills Cemetery Association, besides having played a prominent part in the direction and management of many of the philanthropic activities that have figured largely in the life of Hartford.

TRADE & MARKET CONDITIONS

News of the Trade for the Manufacturer, Wholesaler and Jobber
of Electrical Equipment and Supplies—
Notes on Industrial Activities and Business Methods

MOVEMENT TO DECREASE LOSS THROUGH FAILURES

New York Credit Men Give Further Evidence of
Growing Tendency Toward Co-operation
Within the Industry

Attention is now being directed by a special committee of the New York Electrical Credit Association toward preventing bankruptcies and minimizing losses through failures. The duty of this committee will be to aid in preventing failures wherever possible, and where failures are inevitable to study ways and means of conserving the assets which at that stage rightly belong to the creditors, promoting the most effective sale of the assets and expediting the distribution of dividends. Members of the association have been asked to lend their co-operation by placing before the committee, of which Franz Neilson is secretary, any information which tends to indicate the possible failure of a creditor in order that steps may be taken or, in case failure has already taken place, that the assets may be best conserved for those concerns.

This is but further evidence of the growing tendency throughout the industry to co-operate for the best interests of all. While the number of bankruptcies has not been particularly large, there is no desire on the part of any one to accept a loss where it can be prevented. Information given for the benefit of all will undoubtedly tend to minimize this loss.

Furthermore, there is always the added incentive that where failure impends the concern may be taken in hand promptly and through the injection of sound business principles be put on good footing in comparatively short time. Naturally where such results are achieved it is of advantage to the creditors not only in conserving their assets but also in continuing an outlet for their goods.

MAKING INTEREST CHARGE ON OVERDUE ACCOUNTS

Concerns That Have Had Experience in Following
This Policy Declare It Speeds Up Collections
and Reduces Credit Collection Cost

While the justice of charging interest on overdue accounts is pretty generally conceded, the question of policy is debatable. Aside from the fact that the policy of charging interest is not universal, about the only objection is the chance that the customer may impose more readily upon the seller, feeling that he is paying for the use of the additional time—that the seller is establishing banking facilities.

A certain Chicago jobbing house states that during its experience in charging interest a number of cases wherein the customer has stated by letter or stated to the salesman that he did not understand the attitude of the house in insisting on payment of interest on overdue accounts have arisen. As these cases have come up the house has taken great pains to explain intelligibly to the customer what prompts it to charge interest and what leads it to insist upon the payment of the account promptly even though interest is charged. In most cases it has been possible to convince the customer that the attitude of the house is proper. While this house feels that perhaps it should be conceded that the charging of interest on overdue accounts may have a tendency to increase the number of these, it is stated that this is only a tendency and not a certainty, if the situation is carefully watched and this tendency checked as

it occurs. The surest way of checking it seems to be by letters of explanation to the customer, pointing out that the house is a mercantile institution and is not engaged in financing retail enterprises.

It has been stated that the charging of interest has been definitely found to have a good effect as a collection policy. The house making this statement charges interest from the last of the month following the month in which the goods were purchased, or, in other words, on accounts averaging forty-five days old. In this way the charge goes out at a time when the calling of the customer's attention to the account is very desirable and still at a time when it would not be possible to do this by letter. The charge follows the statement by a few days and goes before any follow-up letters on the account. Where an account first shows a tendency to become overdue, making this interest charge is thought to be the best possible way of jolting into the customer's consciousness the fact that he has exceeded the terms of sale to a point where he is not pursuing a fair, businesslike course.

By watching the results of this policy it has become evident that charging interest actually helps collections. Moreover, the total of the interest charges collected amounts to a respectable sum and is a material item in lowering the cost of handling credits and collections for the company. The interest charges canceled for any cause since the policy has been in effect by this house amount to from one-half to one-third of 1 per cent of the interest charged, and it is believed that this amount will become less and less as this policy becomes more common among jobbing houses.

WHAT THE JOBBER CAN DO TO CONSERVE LABOR

Labor Economies Can Be Effectuated and Better Business Methods Adopted if Employers Realize
Obligations

At the annual meeting of the Pacific Coast Electrical Jobbers' Supply Association, held at Del Monte, Cal., E. J. Wallis, Pacific Coast manager of the Western Electric Company, read a paper on the conservation of labor, from which the following is taken:

"Labor is now employed under conditions more remotely removed from considerations of profit and compensation than ever before. The man who employs labor will feel the sense of responsibility that goes with a trust. He must use it without waste to the best advantage or be considered a slacker.

"Then there is work that has an apparent value but with which we may properly dispense at this time. Perhaps an elaborate acknowledgment of an order may be made simple or done away with entirely. We may have made it a practice to itemize a statement balance beyond the current month. There are some who are advocating now that statements be dispensed with altogether as most buyers pay individual bills and often merely a report of a balance would permit of sufficient check as between accounts. This might at least be done with some of our largest customers. Remittances are made without expectation of acknowledgment or receipts. A style of correspondence can be developed that works automatically to produce short concise letters and eliminate mere words and phrases like 'beg to advise' and 'beg to remain' and complimentary expressions. While we are going to be as courteous as ever, something more than has been the usual practice will have to be taken for granted.

"When there are changes in our organizations and men

leave for the country's service we will try by a detailed analysis of the jobs to determine if the work of, say, two experienced members of whom we are losing one cannot be carried on by the one of experience and two beginners, and for the beginners we may be able to substitute women. All prejudice against women at work has disappeared, and we are astonished at the tasks undertaken.

"We are working between ourselves so free an exchange of stock, not in quantities large but in articles and transactions numerous, that at some centers it would seem that our efforts tended to introduce something expensively better than a reasonably standard service. If we could organize an exchange that would hold forth for an hour or two each day, perhaps by telephone, we might possibly be able altogether to save a considerable amount of time and effort without inconvenience to our customers.

"The character and expense of a sales department in a supply jobbing business is determined as a judgment of the executives of the business. The foundation of the decision will be the amount of sales to which the business aspires.

"The amount of our sales promotion expense will depend on our ambition with respect to the desired volume for our business, and that volume is really our opinion of what is our proper proportion of the total possibilities in our territory. If the determination is reached to attain a greater volume under existing conditions, a larger percentage of realization on the possibilities is of course necessary. It is well to keep in mind that a larger percentage of realization on available business is possible even with a decreased volume of business. If this is not appreciated, an increased and unproductive sales promotion expense may be incurred on the supposition that we are losing our share when the contrary is the true condition.

"The extent to which a jobber will incur sales promotion expense will also depend on the amount and character of the service he figures he can profitably give a manufacturer by introducing new lines, novelties and specialties. Most electrical specialties are labor savers and as such can be introduced as an answer to the labor problem. But those devices that are not labor savers, or those articles that expect a market only to the extent that they can displace some older and more standard device, will probably be classified as luxuries, and the buying public is now being educated against any but justifiable and necessary expenditures."

METAL MARKET SITUATION

Attempts to Have Price of Copper Advanced Officially Will Be Futile—Other Metals Unchanged

It is admitted that the demand for copper for industrial or commercial purposes is being easily met. This is reflected in the reduction in the price of wire base. Producers are endeavoring to have the government or official selling figure of the metal increased at the expiration of the present arrangement, but those in a position to know say the present quotations for the metal will remain unchanged. The sale of rubber-covered, cable and weather-proof wire is active, largely for government work.

No change of any consequence is noted in the old metals market, and the demand is light.

NEW YORK METAL MARKET PRICES

	March 11			March 18

THE WEEK IN TRADE

LITTLE change is noticed in the week's total volume of trade. With the exception of the Far West, building continues slow. The dearth in building has given rise to a very slow movement of stocks normally used by electrical contractors. Delivery conditions show slight improvement here and there. Jobbers' stocks on the whole seem to be in good condition. With the approaching third Liberty loan credits and collections show no appreciable change.

Prices are holding unusually steady. Some lines are advancing, but there are indications of a deterioration of peak prices beginning to set in. Wire is much lower than it was a year ago; for instance, conduit last week softened a few points. Fixtures, it is reported this week, have dropped below the figure at which market quotations for them have recently been made.

NEW YORK

Sellers and receivers of electrical goods, while agreeing that shipping and delivery conditions are improving, are still of the opinion that transportation facilities are far from satisfactory. Hereabouts factory shipments, unless from Connecticut, are delayed, so that stocks in certain lines are greatly depleted. With building operations almost wholly suspended the outlet for many staples is practically closed, or, as one large jobber explained, there is very little regular trade just now. What is going on is what is described as special—that is, government—orders, and they are tremendous in size, the requirements about keeping the nearby market cleaned up on many items. Jobbers, however, are very optimistic. Some price revisions have taken place, but it seems to be the opinion that they are at peak, excepting when it comes to prompt deliveries, and then the quotations for quick service are reported as advancing rapidly.

Collections are rather backward, and the granting of credits is restricted. Trade acceptances are not making the headway desired by distributors and jobbers.

SOLDERING IRONS.—A higher scale of prices, effective April 1, was announced last week on electric soldering irons under the Hoskins schedule.

INSULATORS.—All grades, glasses, sizes and makes are reported at a low level. There is plenty of stock at the mills, but the embargoes have shut off deliveries, which are six and eight months behind.

COLLECTIONS AND CREDITS.—Jobbers, with few exceptions, speak of collections as being slow. Credits remain restricted, and there is a greater volume of cash business than any one can readily recall.

ELECTRIC RADIATORS.—The market having been caught up with, stocks are in full supply again. In fact, reports of an overstock are heard, with a possibility of the goods having to be carried over for the following season's trade.

CONDUIT.—A shortage in all sizes is mentioned as a general condition. Traffic congestion is said to be the basic cause. Four or five cars a day will arrive here, jobbers state, and then there will be none for a couple of months.

ELECTRIC RANGES.—Activity is reported in this line with the approach of warmer weather. Twenty-four heavy-duty electric ranges, capable of taking care of 250 men and costing \$500 each, were purchased by the Navy Department last week.

FAN MOTORS.—Reports of a threatened scarcity in fan motors are in circulation. Some manufacturers are urging

jobber not only to specify their requirements promptly but also to accept shipments at once. It is said that unless cars are plentiful the War Industry Board may interdict all shipments. Stocks are said to be light in this territory, excepting in the case of special company agents. One prominent jobber who has the promise of three cars by May 1 is doubtful whether the delivery will be made. If the situation becomes acute on this account, a further advance in price may be realized.

ATTACHMENT PLUGS.—These goods are in ample supply, as they are easily obtainable from nearby factories in New England.

CABLE.—No building of any account being under way, there is little sale and stocks are heavy with jobbers and dealers.

SMALL MOTORS.—Shipments out of stock are prompt for small motors up to 75-hp. and have been improving. No change in price has occurred.

INDUSTRIAL AND STREET-LIGHTING FIXTURES.—Owing to lack of building operations, sales are far below the average. Factory deliveries are behind three months. Within a few weeks a reduction in price ranging from 5 to 10 per cent has been reported.

HOUSEHOLD SPECIALTIES.—With the growing sales in seasonable articles in this line, such as electric irons, sewing and washing machines, the trade expects still further developments. So far prices have not been affected, and no change is looked for unless the metal market takes an unfavorable turn. A vacuum-cleaner manufacturer, owing to lack of raw material and labor restrictions, has been obliged to hold in abeyance his plan of carrying a full line of household appliances.

CHICAGO

An investigation of business conditions in the territory surrounding Chicago shows markedly the effect of the war on trade. Building activities, except of the industrial sort, are almost nil. The industrial building, however, is on a grand scale. The electrical trade, except that part which relies entirely for its activity on residential building, is very active. Even the contractors with no stores are making out very well by taking up farm-lighting work.

CONDUIT.—The drop in price has in no way affected the conditions of supply and demand. In some places in the Chicago territory jobbers did not make the reduction until more than two weeks after the drop by the manufacturers.

CIRCUIT BREAKERS.—Deliveries from some factories are very slow. Some agents cannot quote better than three months.

TRANSFORMERS.—There is a steady demand by industrial companies.

SOCKETS.—Porcelain sockets have increased slightly in price.

SEWING MACHINES.—The Western Electric Company has increased the retail price of its motor-driven sewing machines \$2.50 per machine.

DOMESTIC APPLIANCES.—The Stirling Electric Company of Minneapolis, a jobbing and dealing concern, has just signed contracts for purchasing washing machines and vacuum cleaners to the aggregate amount of \$1,000,000. The vacuum-cleaner contract is for 9000 machines. It was made with the Ohio company and covers three years' purchases. The washing-machine contract was made with the Gainaday company and terminates in five years. Under its terms the Stirling company is to take 1800 machines this year and is to increase its quota 10 per cent each year, making a total of about 11,000 machines in five years. The contracts do not protect either party as to price, but do give protection on agency, territory and delivery.

FARM LIGHTING.—It is reported that one large company is shipping only one-third of its sales. Other companies are also having trouble getting out enough machines to meet the demand. Electrical dealers everywhere are entering this field of sales in an endeavor to bolster up the business lost because of the falling off in building.

BOSTON

Trade continues in heavy volume, but with jobbers reporting spotty days and a demand that is hard to forecast. Stocks are fairly full at present, despite the handicap of poor transportation conditions. Here and there signs of freer movement of freight on the railroads are to be seen. The coal crisis appears past, normal business hours continue, and more punctual passenger train movement is being experienced. Labor conditions are better than last week, the strike of textile firemen at Fall River being short-lived. The next draft is expected to cut heavily into New England resources in man-power, but time for readjustments mitigates the severity of labor withdrawals from civil life. Collections are good among the manufacturing buyers, but still somewhat slow among the small contractors. The granting of increased freight rates to the Eastern railroads will stimulate general business without question.

There is a strong undercurrent of feeling that the extremely conservative policy of central stations regarding new business will have to yield in the near future to a more liberal one. The pressure of the public for service beyond previously standardized lines is increasing and must be met. Improving relations between central stations and contractors are indicated by the recent establishment of a contact committee representing the New England Section of the N. E. L. A. and the Electrical Contractors' Association of Massachusetts, scheduled to hold a meeting in Boston this week. Prices show little change this week compared with last, but the rising cost of cotton tends toward the lessening of discounts on cable.

HEATING DEVICES.—There appears to be a temporary lull in this class of business, but with the approach of warmer weather a large turnover is expected. Irons are moving well, one jobber reporting that nearly as many units have been ordered since Feb. 1 by certain local purchasers for deferred billing or deferred shipments as were booked from these buyers all through 1917.

MOTORS.—Trade is as heavy as last year, which is saying a good deal. The demand for large motors is literally enormous, units up to 2000 hp. being sought for work related to the war. A better tone appears in the central-station field, notably among hydroelectric companies, which are inquiring more generally for equipment to meet increasing power demands. Prices remain steady and deliveries are better in the smaller sizes. Some stock deliveries have been made lately in sizes ranging from 10 hp. or 7.5 hp. down. Some gaps exist in the lists of available motors, but strenuous efforts to increase factory production are bearing fruit.

TRANSFORMERS.—Deliveries are improving, notably in sizes below 200 kw., where quotations are being made on a two to three months' basis. Below 100 kw. deliveries run from stock shipments to eight weeks. Prices are firm, with no prospect of early change.

METERS.—Large stocks of meters for house lighting are now on hand at the factories, ready for immediate shipment. The demand is rather small at present, and if the housing program in connection with shipyard expansion goes into effect soon, the meters will be "on the job" about as soon as any fittings needed. Prices remain unchanged.

LAMPS.—Conditions are constantly improving, and reserve stocks are now being accumulated in connection with some large orders by central stations which have as yet not been obliged to draw their full commitments from the manufacturers. The 50-watt tungsten lamp is growing in popularity and bids fair to drive the 40-watt and 60-watt units out of the field in due time. "Hooverizing" on light at one end and increased factory facilities at the other are putting a new face upon the lamp supply situation, which but a few weeks ago gave cause for considerable anxiety.

WASHERS.—Popular interest continues in these equipments; the installment plan of sales always appeals to the public, and the lifting of railroad embargoes has begun to help deliveries.

WIRE AND CABLE.—Orders are increasing slightly. Prices remain firm, with a tendency toward discount reductions due to the steady rise in cost of cotton. This is less pronounced in the larger sizes of cable on account of the

higher relative cost of copper. Deliveries are now fairly good. One manufacturer believes that the volume of business which could be realized from shipyard house wiring is nominal from the wire manufacturer's standpoint, pointing out that a million feet of No. 14 wire can be produced by a single factory in a week—an amount which would go a long way toward over-supplying the expected demand from the above source.

CONTRACTING CONDITIONS.—Despite the low volume of building wiring work now seen, contractors are in many cases doing an excellent business in industrial wiring. In the Berkshire Hills district of Massachusetts, for example, many textile and paper products bearing upon war work are being turned out, and local jobbers and wiring establishments report great activity. Larger sizes of conduit for such work have been purchased at high prices from the jobbers. An unusually busy branch of wiring work now being handled by some contractors is the rewinding of railway motor armatures for trolley roads suffering from burn-outs in recent heavy snows. Armatures have been burned out literally by the hundred this winter, and electrical repair houses capable of this class of rewinding are taking over not a little work which cannot be handled quickly enough by the street-railway repair shop itself on account of the excessive amount of motor trouble experienced.

ATLANTA

Governmental activity in shipbuilding, nitrate and powder distillate plants, together with contemplated cantonment extensions and additional construction for aviation purposes, is the overshadowing feature in trade lines at this time. A number of readjustments of outputs of divers industries are still being made in conformity with the exigencies of war, but the general order of things is forward. Meanwhile the magnitude of government requirements in textiles is illustrated anew by reports that 65 per cent of mill capacity is engaged in this business. Charleston, S. C., has definitely been selected by the Shipping Board as the site of one of the two additional shipbuilding yards to be constructed on the South Atlantic Coast. Twelve 9500-ton steel ships will be built at these yards. No definite information is at hand, but it is expected that the other yard will be located at Brunswick, Ga.

A considerable quantity of large apparatus has been contracted for lately, and where the shipment on turbines appeared to be unreasonable large direct-connected engine units have been purchased. Two 4000-kw. turbines have been ordered for the Tennessee Coal & Iron Company's Mobile shipyard. Transformers, switchboards and motors have also been contracted for to take care of the initial installation at Muscle Shoals. A large volume of general supply business is being done at Hadley's Bend, near Nashville, Tenn., for the new powder plant. This condition applies as well to Muscle Shoals.

Manufacturers carrying a general line of supplies are stocking large quantities of marine goods with Atlantic Coast jobbers to handle the present and future extensive demand for this class of material.

ELECTRIC RANGES.—The volume of business is very satisfactory and a steady increase in the demand is noted. Taken as a general average, deliveries are slowing up, and this feature has tended to dampen enthusiasm in certain quarters.

WIRE.—There is a very substantial demand for both rubber-covered and weatherproof. No material change in price has been recorded since the sag several months ago. Deliveries are fair. Stranded goods are hard to get.

KNIFE SWITCHES.—The volume of sales continues steady and local stocks are moving freely. Shipments are arriving steadily.

FUSES.—Activity in this line is about the same. A great number of the motors sold in this territory are provided with overload relays; this feature in itself has tended to offset any increased demand. Shipments are coming in promptly.

INTERPHONES.—Demand is fair, but nothing like the late 1917 business is being transacted. Government demands

and restrictions on this type of apparatus, together with very poor deliveries, have curtailed inquiries and, besides, jobbers and manufacturers are not going after this trade.

SEATTLE

Sales of power apparatus to the new shipyard in Everett and heavy demand for large-sized lamps and floodlighting outfits to yards in the Columbia River district particularly featured the week's business. Jobbers report a noticeable easing up of shipments in conduit and power apparatus. The conduit situation has been serious for months. Arrivals during the week will help temporarily, for the present relief in the freight situation is believed to be but temporary. Government buying for navy yard and cantonments has increased considerably in the past two weeks. The inability of jobbers to obtain deliveries is forcing them to place larger orders to keep stocks filled; merchandise investment therefore has increased materially and nothing like the turnover desired can be expected. Residence building in Puget Sound cities and in Columbia River districts continues exceedingly active. In Seattle and Tacoma building is particularly heavy. Building on a considerable scale has begun in Portland, and real estate values are increasing rapidly. The scarcity of housing facilities for shipyard employees at Astoria, Aberdeen, Hoquiam and other wooden shipbuilding centers is serious. The demand for houses in Spokane cannot be met. Dealers in the Northwest report to jobbing houses a constantly increasing demand for fixtures and house-furnishing material. The movement is expected to reach its peak in early summer, according to conservative jobbers. Some believe demand will continue until winter.

According to statements made by prominent lumbermen, under the eight-hour basis recently adopted lumber production has decreased 10 per cent. Many manufacturers declare that the next few months will show a decrease of 20 per cent. Sawmills in northern Washington on the eight-hour basis are equaling and in some cases exceeding the average output under the ten-hour schedule.

Rigorous steps by railways to stop accumulations of export freight for which no steamship accommodations have been arranged from reaching Seattle are being taken, and the railways may be asked to compel every shipper of export freight in the East to file an affidavit stating that he has secured steamship space on Puget Sound before he will be permitted to load a car.

Lamps of larger sizes are more difficult than ever to obtain, with stocks very low. Sixty-watt sizes and less are coming from factories, giving much easier stocks. The demand from shipyards has been very heavy. Power apparatus is temporarily loosening up because of shipments from the East. Inquiries and orders have been heavy during the past month, motor sales of medium sizes especially increasing rapidly, particularly in the Spokane and Portland territories. Sales to government increased slightly.

SAN FRANCISCO

The past week has been prolific in large jobs of a miscellaneous character. The Hercules Powder Company is adding a new unit to its plant. The city of Sacramento has let a contract for the construction of a new agricultural pavilion to house its annual fair, the electrical work alone being an \$8000 job. Fresno will construct a new 350-room hotel. The Bay Point shipyards will be protected by a new fire protection system utilizing a 50,000-gal. storage tank.

Credit managers report that collections are fairly easy but require careful nursing.

The Pacific Gas & Electric Company has changed its plan of a co-operative range campaign with the assistance of electrical dealers. The new schedule provides for sale to consumers at current list prices with a \$20 allowance for wiring and a 5 per cent cash discount for prompt payment. The installation will be done at the purchasers' expense with the exception of this \$20 allowance, and the power company plans to furnish contractors with special types of fuse blocks and double-throw switches, if required, at their cost plus 10 per cent. The customer will make four monthly payments.

Current Prices of Electrical Supplies

New York and Chicago Quotations

THE prices quoted are those prevailing in standard packages of specified lots on apparatus and appliances in Eastern and Middle West markets at the beginning of business on Monday of this week. They are in all cases the net prices or prices subject to discounts from standard lists of contractors, central stations, dealers and others engaged in the resale of such goods.

Prices in Southern and other nearby markets will rule about the same as those in the Middle West, although slight modifications to cover increased freight and local demands should be expected. In the Far West and on the Pacific Coast the prevailing prices are naturally higher, covering as they must increased

freight and the necessity of larger stocks with increased interest and warehouse charges on account of the distances from sources of supply, infrequent turnover of stock and uncertainty as to delivery of goods in transit. Moreover, the Far West presents a wide variation in demand due to a small population spread over a wide area in agricultural and mining communities, as contrasted with the denser population of the East and Middle West, their nearness to the sources of supply, the more frequent turnover in stocks and the constant demands which arise in industrial centers. Price variations may be due to difference in grade of products of different manufacturers, to local conditions, or to both.

NEW APPARATUS & APPLIANCES

A Record of Latest Developments and Improvements in Manufacturers' Products Used in the Electrical Field

Convertible Electric Lantern

An electric lantern shown herewith operating on a standard flashlight battery is manufactured by the Lindstrom-Smith Company, Chicago. The battery is of sufficient size to give twenty hours of continuous use or forty hours of in-

BATTERY SUFFICIENT FOR TWENTY-HOUR
CONTINUOUS USE

termittent service. It is estimated that it will supply light ten minutes a day for eight months. The entire outfit weighs 24 oz. (680 g.), and is 6 in. (15.2 cm.) by 5.5 in. (14.0 cm.) over all.

Artificial Load for Testing

The illustration reproduced herewith shows a portable "phantom" load manufactured by the Western Electro Mechanical Company, Oakland, Cal. It is used as an artificial non-inductive load for testing alternating-current watt-hour meters in conjunction with a rotating standard or an induction wattmeter. A compression-type carbon rheostat which, it is claimed, will maintain any current between zero and full value is

PORTABLE LOAD FOR TESTING WATT-HOUR
METERS

mounted on the side of the device in series with the secondary. The rheostat is an integral part of the cast case. The equipment is made in rat-

ings of 10 amp., 25 amp. and 50 amp. The 110-220-volt and 220-440-volt equipments are made in these sizes.

Industrial Electric Truck

The industrial electric truck of the motor-in-wheel type, illustrated herewith, has been designed by the C. W. Hunt Company, Inc., West New Brighton, N. Y., and is known as the company's type DF-60. It is built with a drop frame of 4-in. (10-cm.) heavy steel channels, the capacity of the truck being 4000 lb. (1814 kg.). As marketed it is equipped with either thirty Edison G-6 cells or twenty MV-11 "Ironclad Exide" cells. The battery is mounted in a box with recoil spring supports above and below and is placed directly over the driving wheels, insuring maximum tractive effort. In each of the 20-in. (50.8-cm) driving wheels is mounted a 35-volt, 30-amp., 1000-r.p.m. series-wound motor, this method

MOTOR-IN-WHEEL TYPE OF TRUCK

of driving enabling the truck to overcome obstacles to a degree which is unusual.

Series-parallel control is provided, with a range of from 2 miles to 7 miles (3.2 km. to 9.6 km.) per hour in both forward and reverse. The controller, cut-out, fuse and charging socket are mounted in a dust-proof case on the front of the frame, and the operating platform is so designed that when the driver steps off the platform the circuit is immediately opened. Similarly, if the operator removes his foot from the brake pedal, the brakes are immediately applied. The driving wheels are equipped with New Departure ball bearings and 3½-in. by 20-in. (8.9-cm. by 50.8-cm.) solid-rubber tires. The rear or trailing wheels are equipped with 5-in. by 10½-in. (12.7-cm. by 26.7 cm.) solid-rubber tires and Bock roller bearings. The armatures in these machines are of the same diameter as in heavy road trucks of the motor-in-wheel type, but are slightly foreshortened on account of the necessary space requirements.

Two pinions and shafts engage with an equalizing member, applying their power through a gear rack at the periphery of the wheel. The platform of ¾-in. (0.95-cm.) steel plate is only 11 in. (27.9 cm.) from the floor, and is 37 in. by 60 in. (94 cm. by 164 cm.) in size. A cover of ¼-in. (0.6-cm.) checkered steel plate is also provided for the battery box, thereby affording additional carrying space. This truck has an over-all length of 106 in. (269.2 cm.), a width over all of 37¼ in. (95.8 cm.), and an over-all height of 52¼ in. (132 cm.). The turning radius of the outside wheels is 5 ft. 8 in. (1.5 m.), and the truck is of unusually rugged and simple design, built to withstand heavy loads and to operate in narrow and congested areas.

Battery Switch

The Fahnestock Electric Company of Long Island City, N. Y., has recently developed a wooden-base battery switch equipped with Fahnestock spring-clip binding posts. This switch is made in both one and two points. The use of the spring-clip post eliminates all use of tools, it is pointed out, and the device can be wired up instantly. All metal parts of the switch are nickel-plated and are held to the wooden base by means of nickel-plated brass eyelets, eliminating the possibility of loosening.

Large-Size Electric Crane

The electric crane shown in the accompanying photograph is used by the LaBelle Iron Works plant at Steuben-

DYNAMIC BRAKING USED EFFECTIVELY
ON ELECTRIC CRANE

ville, Ohio, and is equipped with General Electric motors. The hoisting is accomplished by a 375-hp. slip-ring induction motor directly coupled to a 40-

direct-current motor. The crane hoist a 14-ton bucket of coal at 10 ft. (152 m.) per minute. The nature of the machine is the dynamic braking obtained by combining the direct-current motor with the alternating current one so that the direct-current unit serves as an exciter. The dynamic braking arrangement here used for the first time on cranes of this size is economical on first cost and has a number of practical operating advantages. Creeping speeds of 110 ft. (33.5 m.) per minute for lowering are obtainable with this crane under ordinary service conditions.

Home Motor

The A. C. Gilbert Company of New Haven, Conn., has developed a home motor that is easily convertible and with different attachments can be made to churn butter, whip cream and eggs, etc.; polish silver and sharpen knives. It can also be furnished with a vibration attachment for massage or converted into an electric fan by attaching guard, blades, etc. The frame is die-cast and the bearings are an integral part of the casting. The motor is nickel-plated and the cast base finished in rich velvet black. It is equipped with a rheostat and plug with rheostat for governing speed. The rheostat has a special lock so that any desired speed may be obtained.

Lighting Unit

The Reflectolyte Company, 914 Pine Street, St. Louis, Mo., is offering to the trade the lighting unit shown herewith, known as the "Ceiling-Bright Reflectolyte."

It consists of a bell-shaped glass diffusing shade, topped with perforated metal cap, which is held firmly in place in the middle of the reflector's base by three small clips. It is pointed out that the light passes through the glass diffusing shade, softly illuminating the ceiling. As in standard types, the reflector is of heavy steel with white polished porcelain enamel fused on

CROSS-SECTION VIEW OF UNIT

using shade, softly illuminating the ceiling. As in standard types, the reflector is of heavy steel with white polished porcelain enamel fused on

layer by layer. The reflector can be detached from chains in a moment by means of a patented device and removed to facilitate cleaning. Being metal throughout, the reflector is break-proof.

Standard Receptacles

The recent additions to the line of "Standard" receptacles made by the Cutler-Hammer Manufacturing Company of Milwaukee, Wis., were designed, the manufacturer states, with the idea of providing a "standard" receptacle for the more popular forms of conduit fittings, as well as for metal molding and for cleat work. The illustration shows how easily these receptacles can be used with the various fittings. Receptacle No. 7753 is intended for use with flush plates having a hinged lid. Nos. 7760 (one-way base) and 7763 (two-way base) are for metal molding. Receptacle No. 7730 can be used in a conduit as shown or with round uni-

RIVETED CONSTRUCTION PREVENTS LOOSENING OF CLIPS

lets or any outlet box having sufficient depth and suitable cover. No. 7766 fits both 1/2-in. and 3/4-in. (12.7-mm. and 19.1-mm.) Paiste taplets, and No. 7713 is for 1/2-in. (12.7-mm.) Obround condulets.

The receptacle for cleat work No. 7727 has proved very popular where open wiring is permitted. It can be readily slipped under the conductors supported by cleats and provides an additional outlet for any appliance. These receptacles are of two-piece construction held together with one screw and nut. Besides being small and neat in appearance, liberal provision has been made for entrance of the wires, and they are very easily wired. Riveted construction is used to mount the contact clips, thus insuring against loosening, as often happens when screws are used. The "standard" straight pull attaching cap shown in the illustration is interchangeable on all "standard" plugs and similar "standard" caps and receptacles of six other manufacturers. This interchangeability is very desirable in the factory or home where electrically operated devices equipped with

various attaching caps are many times connected to plugs and receptacles furnished by several different manufacturers.

Refillable Fuse Plug

The accompanying illustration shows a refillable fuse plug manufactured by the Clemens Electrical Corporation of

REFILLABLE FUSE PLUG HAVING FEW PARTS

Buffalo, N. Y. The plug consists of three parts and the fuse element. To renew the fuse, the two brass rings are unscrewed from the porcelain holder, the blown fuse element slipped out and a new one placed in position. By screwing the rings back the fuse element is held firmly in place.

Vacuum Cleaner

Next to effective removal of dirt from carpets, rugs, etc., the most important point about a vacuum cleaner is its durability. For this reason the turbine principle has been most generally adopted by manufacturers, the typical machine having but one moving unit—an armature upon whose shaft extension is mounted the turbine rotor, the end of the shaft being housed in the bearing. Thus there are no gears, valves, bellows or diaphragms to require maintenance on the part of the user or the central station.

These principles are used in the "Vacuna" cleaner, manufactured by the Kent Vacuum Cleaner Company, Inc., of Rome, N. Y. The turbine used insures a constant flow of air, thereby maintaining the suction pressure at practically the same value whether the opening of the cleaning tube is closed by contact with the surface to be cleaned or whether it is free. The turbine operates at very high speed, and is carefully balanced so as to run steadily without vibration. Westinghouse alternating-current universal motors are used. This motor is designed on the principle used in the manufacture of very large motors, such as those used in railway work, and is of the concentric compensating type which insures very long brush and commutator life. Variation of speed at the same load between direct-current and alternating-current service is very small.

Electric House Pump Automatically Controlled

A small electrically driven pump for supplying rain water to residences is shown in the accompanying illustration. It may also be used for a general water supply where city service is

PUMP AND MOTOR MOUNTED ON SAME BASE

not available. The pump and motor are mounted on a cast-iron base and are connected by a belt. The pump is a slow-speed type. An automatic controller switch is connected with the discharge pipe and is set to operate between pressures of 20 lb. (1.4 kg. per sq. cm.) and 40 lb. (2.8 kg. per sq. cm.). It can be adjusted, however, to operate between any pressures that may be predetermined.

The pump is manufactured by the Crestline Manufacturing Company, Crestline, Ohio, and is equipped with a Robbins & Myers motor. The outfit is made in two capacities—125 gal. per hour and 250 gal. per hour, and in both sizes it will operate against a head of 50 lb. per square inch (3.5 kg. per sq. cm.).

High - Speed Sphere - Gap Graded-Resistance Lightning Arresters

The accompanying illustration shows a new type of high-speed sphere-gap graded-resistance lightning arrester manufactured by Schweitzer & Conrad, Inc., Chicago. Lightning arresters, it is pointed out, to be effective in protecting electrical apparatus must offer instantaneous relief from abnormal voltages and at the same time prevent the flow of excessive dynamic or generating current after the abnormal potential has been dissipated. The gap shown is the smallest at the upper end of the converging portion of the horns, where the maximum resistance is inserted. At the lowest or "no resistance" step the gap is of considerably greater extent.

The manufacturers claim that this arrangement has several important advantages. With any potential rise on the system protected by the arrester, the arc will start across the smallest gap with all of the resistance in series.

If the power represented by the discharge is small, the current flowing through this gap and comparatively high resistance may be sufficient to keep the line voltage down approximately to normal. If the current flowing through the gap of maximum resistance is not sufficient to keep the line voltage down, the arc will break across the next lower step and a larger current will flow across this gap. If this current is still insufficient to keep the voltage at a safe value, then the next lower step will be across, and so on, until the "no resistance" or lowest step is reached, when a practically unlimited electric current is allowed to flow to ground.

When the particular step is reached where sufficient current will flow to dissipate the potential rise, the voltage will be reduced to its normal value, and the arc will then tend to rise along the converging part of the horn, being driven upward both by the heated air and by the electromagnetic effect. As the arc rises along the converging part of the horn the dynamic or generator current is cut down in value as the resistance in circuit is increased step

BAKELITE TUBES PROTECT RESISTANCE FROM EFFECTS OF WEATHER

by step until the diverging portions of the horns are reached, where it will rise and lengthen until the arc breaks. The resistance units are inclosed in high-grade Bakelite tubes which protect them effectively against the weather, so that the arrester can be used outdoors without any protecting coverings. By loosening two bolts of a clamp on the top of the porcelain insulator cap the live horn can be adjusted to meet any condition.

Portable X-Ray Set for Field Service

During 1917 the research laboratory of the General Electric Company made some experiments and developments in X-ray apparatus of interest to the medical and surgical professions. The concrete result of these efforts was a portable X-ray outfit, in order that troops in active service at a distance from base hospitals might have the benefits of X-ray examination promptly available. This was accomplished by a process of elimination through a series of tests which resulted in the final assembly of the most suitable

products of several manufacturers which are used in connection with the Coolidge tube. Particular care was taken to pick out those elements which were in actual production and available for immediate use.

The equipment consists of a single-cylinder, air-cooled gasoline engine direct-connected to a 1-kw. direct-current generator provided with slip-rings, a main X-ray transformer, a filament transformer for lighting the filament of the Coolidge tube, a voltmeter and milliammeter, the necessary controls and switches and a special radiator type of Coolidge tube capable of rectifying its own current. Variation of X-ray output is obtained by variations of engine speed. The carburetor of the engine is controlled through a solenoid, and the necessary changes in speed are effected by means of a simple resistance unit installed at the head of the operating table when the outfit is in process of utilization.

For radiographic work the set will deliver 10 milliammeters at a voltage corresponding to a spark of 5 in. (12.7 cm.) between points. For fluoroscopic work the current is reduced to 5 milliammeters, the voltage remaining the same.

Owing to the rectification characteristics of the Coolidge tube no separate rectifier is required. The entire equipment, including the operation table, can be readily assembled or disassembled for transportation, the complete set having a net weight of about 860 lb. (390.1 kg.) While sets for similar service have been developed in Europe under the spur of urgent need, the equipment here referred to constitutes the first American portable X-ray outfit of this capacity to be manufactured.

Projector for Floodlighting

A powerful floodlight projector especially adapted to protective night lighting has recently been placed upon the

CROSS-SECTIONAL VIEW OF REFLECTOR FOR FLOODLAMP

market by the National X-Ray Reflector Company of Chicago. The projector ordinarily uses a 400-watt gas-filled flood-lighting lamp. The socket is adjustable and can be controlled from the outside so that the beam of light can be varied from a 12-deg. to a 30-deg. angle. A swiveling and tilting device at the base plate make the projector flexible in operation.

Trade Notes

THE ALBERT EMANUEL COMPANY, electric utility operator, 710 Schwind Building, Dayton, Ohio, has moved its offices No. 61 Broadway, Room 712, New York City.

W. F. GEORGES, formerly of the Western Electric Company of Cincinnati and New York, has joined the selling organization of the Trumbull Electric Manufacturing Company, with headquarters at the New York office, 114 Liberty Street.

J. G. SANDIDGE, who has been in the Chicago office of the Cooper Hewitt Electric Company of Hoboken, N. J., as district salesman for the last few years, is now at 11 Majestic Building, Milwaukee, Wis., and will look after Cooper Hewitt matters in that vicinity.

CYRUS SCHUMACHER of Bluffton, S. C., announces that he is going to manufacture air motors to be used in charging storage batteries for farm lighting and especially for irrigating purposes. Mr. Schumacher recently severed his connection as superintendent of the Bluffton Light & Water Works.

CHARLES G. ROBIN, INC., 48 Warren Street, New York City, announces its purchase of the Indesco Lighting Fixture Company at 47 Warren Street. The entire electrical stock of the former concern will be moved to the latter address at once, where complete line of electrical supplies and fixtures will be carried.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY announces at its Pittsburgh service department has moved from its former location on Amber Avenue to new quarters at 6905 Susquehanna Street, in the Homewood district of Pittsburgh. Express and freight should be assigned to East Liberty, Pa., via the Pennsylvania Railroad. The automobile equipment service department has also moved to the new location.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY of East Pittsburgh, Pa., has recently secured the exclusive sales agency for the United States for Frankel solderless connectors. Manufacturing facilities have been increased by the Frankel Connector Company in order to care for the new business to be secured through the Westinghouse sales organization. The Westinghouse company will act also as a distributor of Frankel testing clips.

THE MANHATTAN ELECTRICAL SUPPLY COMPANY of Boston, Mass., at the annual meeting, elected Burtis H. Ellis first vice-president and treasurer, James Ryan second vice-president, N. F. Johnson second vice-president and assistant treasurer, Edgar Whitmore secretary, Rufus Wilbur, Arthur Guilds and Frank Pierce directors. A statement of earnings which is expected in a few days will, it is estimated, show profits after taxes applicable to dividends of nearly \$600,000.

WILLIAM T. PRICE resigned as manager and chief engineer of the De La Vergne Machine Company, oil engine department, recently, to become president of the P-R Engine Company of New York and second vice-president of the Rathbun-Jones Engineering Company of Toledo, Ohio, which will undertake the sale and manufacture respectively of Price-Rathbun stationary and marine oil engines built in accordance with a new principle of fuel injection developed by Mr. Price in the last few years. The P-R Engine Company has its main office at 110 West Fortieth Street, New York, and other offices in Philadelphia, Baltimore and Toledo.

THE FEDERAL SIGN SYSTEM (ELECTRIC), Chicago, the building of which was the scene of a severe fire last week, reports that it has entirely recovered from this unfortunate accident. The fire was discovered at 5:40 o'clock in the evening of March 13, and defied the firemen until 10 o'clock. The rooms which were wrecked were the tin shop, the machine shop and an auxiliary stock room used for storage of excess material. While the office suffered considerable damage from water, no records were lost. The office staff was doing business as usual in an adjacent building at 10 o'clock on the following morning. The company's sign, fuse, washing-machine and vacuum-cleaner departments were not damaged. While the loss occasioned was of the magnitude of \$200,000, it was fully covered by insurance. H. L. Markham, general manager of the company, stated that it was particularly fortunate that the fire broke out where it did rather than in some other location, since the departments destroyed were those in which work is now most

slack and can be most easily maintained by transferring activities to outside shops. Space to take care of this work in an adjacent building has already been arranged for. The fire, it is stated, will not have any adverse effect on deliveries of goods to the company's customers.

CAPTAIN RICHARD P. HENRY, late of the United States Army, has joined the selling forces of the Square D Company of Detroit, manufacturer of steel inclosed safety switches, and has been appointed to the Indiana territory, with headquarters at Indianapolis. He spent three years at Purdue University, since when he has been engaged in various branches of engineering work. His first position was that of assistant engineer for the Terre Haute, Indianapolis & Eastern Traction Company, Terre Haute Division. In 1912 Captain Henry joined the Santa Susana Syndicate, Los Angeles, Cal., in the capacity of engineer and assistant geologist, and later entered the contracting business for himself, with offices at Chicago. He finally enlisted in the Engineering Corps of the United States Army, from which he was recently given an indefinite leave of absence on account of physical disability.

Trade Publications

FANS.—Marelli fans for the 1918 season are illustrated and described in a circular prepared by H. Boker & Company, Inc., 101 Duane Street, New York City.

ARTIFICIAL LOAD.—The Western Electric Mechanical Company of Oakland, Cal., has issued a circular describing its "phantom load" for testing alternating-current wattmeters.

MOTOR NECESSITIES.—The Emil Grossman Manufacturing Corporation of Brooklyn, N. Y., is distributing its catalog No. 10, descriptive of its "Ever Good" motor necessities.

ELECTRIC LANTERN.—The Lindstrom, Smith Company of Chicago has issued a one-leaf circular illustrating its White Cross Electric Lantern and showing the uses to which it can be put.

ILLUMINATING GLASSWARE.—The Tarentum Glass Company of Tarentum, Pa., has issued a thirty-two-page catalog illustrating and describing its Tara glass products for direct and indirect illumination.

CABLE CLAMPS.—W. N. Matthews & Brother, Inc., St. Louis, Mo., has issued a one-page circular entitled "Labor Conservation." The circular explains the use and shows illustrations of the Matthews wire and cable clamps.

GENERATING SETS.—The Universal Motor Company of Oshkosh, Wis., has prepared bulletin No. 26, showing its 4-kw. generating sets. Photographs showing the various uses to which the generator sets may be put are printed.

EXPANSION JOINTS.—A circular from the Nuttall one-piece expansion joint which is being distributed by Nuttall of Pittsburgh, Pa., refers to an expansion joint which requires no packing and eliminates loops and bends in the pipe lines.

REFRIGERATING MACHINERY.—Bulletin No. 17 of the De La Vergne Machine Company of New York City shows actual installations of the De La Vergne ammonia condensers. The bulletin shows both the counter-current and parallel-flow types.

OIL FUSE CUT-OUTS.—The D. & W. Fuse Company of Providence, R. I., has recently issued a well-illustrated catalog showing the different types of fuse cut-outs which it manufactures. The booklet contains the rating of the different fuses and also a price list. Several actual installations are shown.

LIGHTING FIXTURE.—The Beardslee Chandelier Manufacturing Company of 216 South Jefferson Street, Chicago, has prepared a full-page circular showing the construction and method of support of its "quick-action" ceiling ring. Several sizes of ceiling rings are shown, together with various styles of glassware.

REFLECTOLYTE.—This is the name of catalog No. 4 issued by the Reflectolite Company, 914 Pine Street, St. Louis, Mo. The bulletin is well illustrated and shows a number of semi-indirect lighting units made by the company. The illuminating requirements of public, private and industrial institutions are well outlined.

MODERN METHODS IN TEXTILE MILLS.—Under this name the Westinghouse Lamp Company, 165 Broadway, New York

City, has issued a publication showing the need of better lighting in textile mills. It gives pictures comparing the effect of ill-lighted mills and well-lighted mills. The booklet is bound with a substantial cloth cover.

AUTOMATIC SKIP HOIST.—The Otis Elevator Company, Eleventh Avenue and Twenty-sixth Street, New York, has issued a bulletin referring to its skip hoists, which are automatically operated. Different types of skip hoists, their layout, and some typical installations in manufacturing plants, coal and coke plants, gas, electric light and power stations are shown.

SINGLE-PHASE MOTORS.—The Century Electric Company of St. Louis, Mo., has issued a catalog of its single-phase self-starting motors which are rated at 0.1 hp. to 30 hp. and which are of the repulsion-start induction type. Cross-section views of several types of motors are shown in the booklet. Actual installations and applications of the single-phase motors are also shown.

CIRCUIT BREAKERS.—The Automatic Reclosing Circuit Breaker Company of Columbus, Ohio, has recently issued bulletin No. 30, entitled "Automatic Reclosing Circuit Breakers and Relays for the Protection of Direct-Current Circuits." The bulletin gives a general description of the principle and applications of the circuit breakers and shows actual installations in several mines. It is well illustrated and contains several wiring diagrams of the apparatus.

PUMPS.—The C. H. Wheeler Manufacturing Company, Eighteenth Street and Lehigh Avenue, Philadelphia, is distributing a booklet entitled the "Radojet Air Pump." The bulletin is well illustrated, giving the outside views of various size injector-type pumps and showing the application of the so-called air "pump" in a power plant. The general arrangement of the piping system for air removal from condenser, etc., is also shown. Steam tables are included.

FARMERS' ELECTRICAL HANDBOOK.—This is the title of a valuable book published by the Western Electric Company on the application of electricity to farm service. Besides being a complete catalog of the apparatus and appliances used for farm lighting, the booklet shows how to wire a house and how to start telephone companies in rural districts. The book mentioned is the fourth edition of the "Farmers' Electrical Handbook," the previous editions being issued in 1916 and 1917.

New Incorporations

THE SUPREME ELECTRICAL CONSTRUCTION COMPANY of Brooklyn, N. Y., has been incorporated with a capital stock of \$5,000 by E. B. Cohen, H. Rothenberg and H. Bertinger, 135 Broadway, New York, N. Y.

THE HARTWELL - RADEMAEKERS MANUFACTURING COMPANY of Newark, N. J., has been incorporated by William H. Rademaekers and Albert E. Hartwell of Newark. The company is capitalized at \$150,000 and proposes to manufacture electric motors.

THE MERRILL MANUFACTURING COMPANY of Boston, Mass., has been chartered with a capital stock of \$50,000 to manufacture spark plugs and mechanical and electrical appliances. William J. Russell is president and Thomas B. Sweeney, 50 State Street, is treasurer.

THE STANLEY ENGINEERING COMPANY has filed articles of incorporation under the laws of the State of Delaware with a capital stock of \$4,000,000 for the purpose of installing steam, electric and hydraulic plants, etc. The incorporators are: C. L. Rimlinger, M. M. Clancy and F. A. Armstrong of Wilmington, Del.

THE VICTORIA SALES CORPORATION of New York, N. Y., has been incorporated by A. Ornstein, 1838 Seventh Avenue, New York City; P. A. Larter, Bensonhurst, N. Y., and F. A. Schilling, 647 Academy Street, New York, N. Y. The company is capitalized at \$30,000 and proposes to manufacture electric lamps for automobiles, etc.

THE CINCINNATI SPECIALTY MANUFACTURING COMPANY of Cincinnati, Ohio, has been incorporated with a capital stock of \$25,000 by J. E. Snyder, S. S. Oakley and others. The company formerly operated a plant at Powers Street and Sylvan Avenue under a partnership. One of the specialties manufactured by the company is an automatic extension reel for electric lamps.

New England States

BURLINGTON, VT.—The Electric Light Commissioners are considering the question of renewing the contract with the Burlington Light & Power Company for furnishing hydroelectric power for the municipal electric light plant, which expires April 1.

CAMBRIDGE, MASS.—Plans have been completed and bids taken by the Cambridge Electric Light Company, 16 Blackstone Street, for the construction of and addition to its power plant, about 30 ft. by 40 ft., one story high.

EAST HAMPTON, MASS.—Work has begun on the construction of a new power plant and switchroom at the works of the Glendale Elastic Fabrics Company, to cost about \$10,000. Contract has been awarded to the Casper Range Construction Company, 29 Bond Street, Holyoke.

WORCESTER, MASS.—Plans are being prepared by the W. H. Sawyer Lumber Company, 66 Lincoln Street, for the construction of a power house in connection with its proposed new plant. The cost of the work is estimated at \$70,000.

FORESTVILLE, CONN.—The power plant of the Peck & Young Manufacturing Company was completely destroyed by fire on March 10.

TERRYVILLE, CONN.—At the annual town meeting it was voted to change the street lighting system from arc lamps to incandescent.

Middle Atlantic States

BINGHAMTON, N. Y.—Contracts have been awarded by the Binghamton Light, Heat & Power Company for furnishing energy to the amount of 300 hp. to two large manufacturing plants, due to the destruction of a portion of a dam in the Susquehanna River rendering useless the water-power plants of the two companies.

BUFFALO, N. Y.—Plans have been prepared by the National Aniline & Chemical Company for the construction of an addition to its power house, to cost about \$8,000.

BUFFALO, N. Y.—Bonds to the amount of \$60,000 have been authorized by the City Council to provide funds for the proposed improvements in the police and fire-alarm systems, including the installation of underground conduits to replace overhead wires.

LOCKPORT, N. Y.—Notice has been filed by the Lockport Light, Heat & Power Company with the Public Service Commission of an increase in capital stock from \$150,000 to \$350,000, the proceeds to be used for extensions, etc., to its system.

NEW HAMPTON, N. Y.—The contract for the construction of a new power house at the local reformatory for the Department of Correction, Municipal Building, New York, has been awarded to Nelson & Miller, West Main Street, Middletown.

NEW YORK, N. Y.—Plans are under consideration by the New York Telephone Company, 15 Dey Street, for building an addition to its telephone exchange building at West New Brighton.

NEW YORK, N. Y.—The National Lead Company has awarded a contract to Charles E. Knox, 101 Park Avenue, New York, for electrical work in connection with its new six-story factory building, to be erected at Marshall and Gold Streets, Brooklyn.

NIAGARA FALLS, N. Y.—Contract has been awarded by the National Carbon Company to the Osborn Engineering Company of Cleveland, for erection of additional factory buildings at its plant in Niagara Falls, including a six-story building, 54 ft. by 193 ft., a two-story 20 ft. by 114 ft., and two one-story buildings, 70 ft. by 144 ft. and 49 ft. by 70 ft., to cost about \$200,000.

JERSEY CITY, N. J.—Bids will be received by the Boulevard Commission until April 3 for furnishing new lamps, generators and other appliances for use in connection with the proposed improvements to the electric-lighting system on the Boulevard.

NETCONG, N. J.—Plans are being considered by the Council for the installation of a new ornamental lighting system on Main Street. Lamps of larger candlepower will be installed.

NEWARK, N. J.—A permit has been taken out by Maas & Waldstein, Inc., Avenue R, for the construction of an addition to its plant and for improvements to boiler house. The cost of the entire work is estimated at \$12,000.

TRENTON, N. J.—Plans for the construction of a new municipal hydroelectric power plant, to be located on Sanhican Creek, is under consideration by the City Council.

Construction

News of Projects, Plans, Bids and Contracts. Notes on Work Under Way

DELAWARE WATER GAP, PA.—The Pennsylvania Utilities Company of Easton has applied to the Borough Council for a franchise to furnish electricity for lamps, heaters and motors in Delaware Water Gap for a period of 15 years. Application was also made to the Council for permission to tie in the 2300-volt transmission line of the utilities company, which extension was made from the Analomink Paper Company about a year ago.

ERIE, PA.—The Council has appropriated \$4,756 for the construction of a conduit for low and high tension wires through the Parade Street subway, extending from Fourteenth to Seventeenth Street.

NANTICOKE, PA.—Contract has been awarded by the board of managers of the State Hospital to John Curtis & Company, 1 Hickory Street, Wilkes-Barre, for the construction of a new power house, about 50 ft. by 65 ft., one story high.

PHILADELPHIA, PA.—Contract has been awarded by Andrew J. Sauer & Company, architects, to the Coneen Construction Company for a one-story power house to be erected at 2626 Martha Street, for M. A. Lieberman.

STEELTON, PA.—Plans are being considered by the Bethlehem Steel Company for the installation of four new boilers of 250 hp. each in the new addition now under construction at its works near Swatara Street.

TOPTON, PA.—The Bowers Electric Company has petitioned the Public Service Commission for approval of a franchise granted by the borough of Tipton to supply electrical service in the borough.

TYRONE, PA.—The West Virginia Pulp & Paper Company has awarded a contract to John G. Livingston, Jr., 70 East Forty-fifth Street, New York, for electrical work in connection with the construction of its new manufacturing plant, consisting of eight large buildings, under construction at Tyrone, at a cost of about \$500,000.

BOWERS, DEL.—Steps have been taken to organize a company to install and operate an electric-light plant in Bowers. W. E. Kelly is reported interested in the project.

BALTIMORE, MD.—Preparations are being made by the Consolidated Gas, Electric Light & Power Company for the erection of a branch power station in Linthicum, 40 ft. by 26 ft., to cost about \$7,000, for which bids have been submitted.

ELLICOTT CITY, MD.—A bill has been introduced in State Legislature authorizing the Commissioners of Ellicott City to issue bonds for the installation of a municipal electric-light plant, providing a majority of taxpayers ask for same.

BLUEFIELD, W. VA.—Plans are being considered by the City Council for improvements to the street-lighting system. It is proposed to discard the arc lamps now in use and install incandescent street lamps.

NEWPORT NEWS, VA.—Plans are under consideration by the Chesapeake & Potomac Telephone Company for the erection of a new telephone exchange plant. P. G. Burton, 108 East Lexington Street, Baltimore, Md., is engineer.

WASHINGTON, D. C.—The Potomac Electric Company is planning to build a boiler house on Benning Road, to cost about \$75,000.

WASHINGTON, D. C.—The Bureau of Yards and Docks, Navy Department, Washington, D. C., has awarded contract to the General Electric Engineering Company, 317 Canal Street, New York, N. Y., to install an electric-light and power system at the navy yard at Anacostia, D. C., to cost \$10,539.

WASHINGTON, D. C.—Contract has been awarded by the United States Food Administration to the George A. Fuller Company, Munsey Building, Washington, D. C., to erect an office building at Twentieth and D Streets, N. W., two stories, 155 ft. by 334 ft., with five courts, 2 ft. by 105 ft., to cost about \$150,000.

WASHINGTON, D. C.—Bids will be received at the office of the purchasing agent of the Post Office Department, Washington, D. C., until April 9, for furnishing electrical supplies (motors, carbons, fuses, etc.). Blanks for proposals with specifications may be obtained upon application to the purchasing agent.

WASHINGTON, D. C.—Bids will be received at the office of the Commissioners of

the District of Columbia, Washington, D. C., until April 2, for furnishing and delivering during the fiscal year beginning July 1, 1918, and ending June 30, 1919, the use of the various branches of the government of the District of Columbia supplies as follows: Electrical supplies, chemical laboratory supplies, etc. Form of proposed specifications and necessary information may be obtained from the purchasing office of the District of Columbia, Room 320, District Building, Washington, D. C.

WASHINGTON, D. C.—Bids will be received at the Bureau of Supplies and Accounts, Navy Department, Washington, D. C., for furnishing at the various navy yards and naval stations supplies as follows: Brooklyn, N. Y., Schedule 1725—134,000 ft. leaded and armored, plain interior communication cable, 870,000 ft. leaded and armored, plain, duplex double-conductor wire, 140,000 ft. armored, duplex double conductor wire, 260,000 ft. plain single conductor wire, 158,000 ft. soft steel leaded and armored, single-conductor wire; Schedule 1724—400,000 ft. twin lamp cord, 50,700 ft. lead-covered wire, 202,500 ft. duplex rubber-covered wire, 37,000 lb. weather proof wire on reels. Philadelphia, Pa., Schedule 1725—miscellaneous plain and armored magnet wire. Application for proposal blanks should designate the schedule desired by number.

North Central States

MARQUETTE, MICH.—Plans are being prepared by the Arnold Company, 10 South La Salle Street, Chicago, Ill., for the construction of a plant, consisting of 10 buildings for the Lake Superior & Ishpeming Railroad Company, to cost about \$400,000. Bids, it is understood, are now being received by the architects for construction of the buildings.

NORTHPORT, MICH.—Plans, it is reported, have been completed by the Electric Point Mining Company for the installation of an aerial tramway, connecting the shaft with the wagon road at Leadpoint, distance of 2¼ miles. It will have a capacity of 20 tons an hour and will cost from \$40,000 to \$50,000.

PORT HURON, MICH.—The City Commission is considering a proposal for the installation of electrically operated pumps to replace the steam pumps at the water works station. The cost is put at \$19,000.

READING, MICH.—The Council is considering submitting the proposal to issue \$8,000 in bonds for improvements to the water and light systems to the voters.

CARTHAGE, OHIO.—Contract has been awarded by the Polak Steel Company of Cincinnati to the M. Marcus Building Company of Cincinnati for the construction of an addition to its power plant at Carthage.

CLEVELAND, OHIO.—Bids will be received at the office of the commissioner of purchases and supplies, City Hall, Cleveland, until March 29, for valves for the division of light and heat. Specification may be obtained at the office of the division of light and heat.

CLEVELAND, OHIO.—The Cleveland Electric Illuminating Company has awarded contract for construction of a one and two story reinforced concrete steel and brick power house, 150 ft. by 200 ft., to be erected on East Seventieth Street, to the National Concrete Fireproofing Company, Citizen Building. The cost is estimated at about \$1,000,000.

HAZARD, KY.—The Perry Coal & Lumber Company is contemplating the installation of an electrically-operated plant for coal development on the Louisville & Nashville Railroad in Perry County. Frank Nudelman and others of New York, N. Y. are reported interested in the project.

ATTICA, IND.—The municipal electric light and water works plant was destroyed by fire on March 9, causing a loss of about \$60,000. At present the city is without electrical service and the water supply is inadequate. Steps have been taken to rebuild the plant and \$100,000, or as much as needed, was pledged by the business men.

BIGGSVILLE, ILL.—The Biggsville Light Company is contemplating changing its system to alternating current, single phase, and extending its service to two small towns and farmers along the line which will require about a 75-kva., single phase, 2200 or 1100-volt machine. D. V. Lee is vice-president.

CHARLESTON, ILL.—Bonds to the amount of \$20,000, the proceeds to be used for improvements to the municipal electric light plant and water-works system, have been authorized.

CHICAGO, ILL.—The Drainage Board has decided upon an expenditure of \$50,000 for rehabilitating the electrical system. The report of the engineers estimated the cost of the work at \$200,000.

CHICAGO, ILL.—The War Department planning to erect several large warehouses in Chicago for army supplies. Contract has been awarded to the E. W. Sproul company, 1129 West Thirty-fifth Street, for the erection of a six-story, 500 ft. by 600 ft., army distributing warehouse, with a three-story tower and one-story power house. Thirty-ninth Street and Ashland Avenue. No units are to be built at once at a cost of about \$2,800,000. Work has begun on the above buildings. George C. Nimmons, 2 South Michigan Avenue, will have charge as supervising architect for the government.

MOUNT OLIVE, ILL.—At an election to be held April 16 the proposal to issue \$8,000 bonds for improvements to the municipal electric-light plant will be submitted to the voters. It is proposed to equip the waterworks pumping station with electrically-operated pumps. W. S. Merkle of St. Louis, Mo., is engineer in charge of the proposed improvement.

SIDNEY, ILL.—The Village Board has accepted the proposal of the Homer (Ill.) Electric Light Company to supply electrical service in Sidney for one month. If the service is satisfactory the local plant will be closed down and energy will be supplied from the Homer system.

CLINTONVILLE, WIS.—Work has started on the construction of a hydroelectric power plant on the Embarrass River, about 12 miles north of the city, for the J. P. Stewart Tractor Company of Clintonville. The plans provide for an initial installation of 750 hp. Electricity generated at the plant will be transmitted to the new tractor factory in Clintonville.

GREEN BAY, WIS.—Contracts have been awarded by the Northwest Engineering Works of Green Bay for the construction of a new fabricating shop, 30 ft. by 10 ft., and an addition to the boiler shop, 10 ft. by 150 ft. Two floors of an adjoining building will be remodeled into mold lofts. Considerable equipment is being purchased for the company, including a 10-ton jib crane, two furnaces and an electric air compressor. The company has contracts for construction of several steel ships.

MILWAUKEE, WIS.—Bids, it is understood, will soon be called for by the Board of Directors for the construction of a new high school building to cost about \$450,000, including manual training and domestic science departments. Frank M. Harbach is secretary.

WAUSAU, WIS.—Bids, it is expected, will soon be asked by the board of education for the construction of the first unit of the proposed new industrial and vocational training institute, to cost about \$50,000. The first building will be 90 ft. by 200 ft.

BOYDEN, IOWA.—Veenschoten Brothers, owners of the local electric-lighting system, are erecting an electric transmission line to Sheldon, where they will purchase electricity from the Iowa Light & Power Company. Energy will be transmitted at 6600 volts, 60-cycle, single-phase and stepped down to 100 volts at Boyden. The local system will be changed from direct to alternating current. It is expected to have the line completed about April 1.

BOSSIAN, IOWA.—The local electric-light and power plant, owned by Harry Bullard, has been purchased by A. G. O'Rear of Mason City. The new owner, it is understood, will make improvements to the system.

PALMER, NEB.—The local electric-light plant was recently destroyed by fire.

CHAPMAN, KAN.—Work will begin on the construction of the new transformer station of the United Telephone Company. A number of important improvements, it is understood, will be made by the company this spring.

MORAN, KAN.—The Municipal Light and Water Department is considering the question of supplying electricity in Bronson for domestic and power purposes. If the project goes through a 100-hp. oil engine will be required in addition to the present equipment, to be installed within three to six months. Correspondence is solicited from parties who have a second-hand 60-cycle, three-phase, 2300-volt alternator of 5 kva. capacity to sell. R. S. Parsons is general superintendent.

OAKLEY, KAN.—The erection of an electric transmission line from the municipal electric-light plant to Colby is under consideration by the city of Oakley to secure electricity to operate the local system.

PITTSBURG, KAN.—Bids will be received by the Sisters of St. Joseph, care of W. W. Van Meter, Caldwell-Murdock Building, Wichita, until March 27 (extension of date) for construction of addition to Mount Carmel Hospital, two and three stories and basement, 50 ft. by 136 ft. Separate bids

to be submitted on heating, electric wiring, plumbing, elevator and vacuum cleaner, etc. The cost is estimated at \$100,000.

YATES CENTER, KAN.—The municipal electric-light plant was wrecked by a tornado on Feb. 28.

Southern States

SOUTHPORT, N. C.—The property of the Southport Electric Light & Power Company is reported to have been purchased by J. G. White & Company, 43 Exchange Place, New York, N. Y., for \$50,000. Improvements, it is understood, will be made to the system, involving an expenditure of about \$20,000, and will include the installation of a 20-ton ice plant.

ATLANTA, GA.—The Board of Water Commissioners has rejected the bid of the Georgia Railway & Power Company to furnish electricity for a proposed new pumping plant, at an annual charge of \$58,000. The Council has appropriated \$34,500 for the construction of a pump having a capacity of 15,000,000 gal. per day.

ATLANTA, GA.—The Department of Justice has asked for an appropriation of \$1,000,000 for the installation of 500 light and medium weight looms, 1050-hp. electric motor drive, etc., for weekly capacity of 116,000 lb. of cotton duck. This machinery is to equip a 457-ft. by 210-ft. reinforced concrete brick construction weave mill, one story, constructed by prison labor, at a cost of \$129,500, at the United States penitentiary, Lockwood, Greene Company of Atlanta, Ga., and Boston, Mass., are architects and engineers.

MACON, GA.—Contract has been awarded by the War Department, Cantonment Division, Washington, D. C., to W. Z. Williams, Georgia Casualty Building, Macon, for construction of the proposed hospital buildings at Camp Wheeler, to cost from \$150,000 to \$170,000.

ANNISTON, ALA.—The War Department, Washington, D. C., has awarded the Crowell Construction Company of Chicago, Ill., the contract for construction of buildings for hospital at Camp McClellan, to cost about \$500,000.

BIRMINGHAM, ALA.—The Alabama Interurban Railway Company, which is planning to build an electric railway from Birmingham to Lock No. 17 on the Warrior River, a distance of about 20 miles, is also contemplating building branches, one to Patton Ferry, 5 miles long, and to Shoal Creek, 15 miles. Another extension to Lock No. 16 and Davis Creek is also under consideration.

LITTLE ROCK, ARK.—Bids will be received by the school board until March 28 for construction of a grade and junior high school building, to cost about \$100,000. Separate bids to be submitted on wiring, plumbing and heating.

JENNINGS, LA.—An election will be called to submit the proposal to issue bonds for the installation of an electric-light plant, ice factory and sewer system to the voters.

PLEASANTON, TEX.—The Town Council has decided to take over the local electric plant for a period of 60 days to test municipal ownership. If it proves satisfactory the plant will be purchased by the city.

Pacific and Mountain States

CENTRALIA, WASH.—F. M. Lewis and others have organized a company for the purpose of manufacturing and using a propeller type current water motor, which will operate pumping machinery for placing water on desert land. The machine was patented by Mr. Lewis.

CHEHALIS, WASH.—The proposal to grant O. B. Anderson of Portland, Ore., a franchise to supply electricity for lamps and motors in Chehalis will be submitted to the voters at a special election to be held April 20. The Council recently refused to grant this franchise on the ground that it would result in a duplication of systems. Upon refusal of the Council a petition was circulated by the promoter, and sufficient signatures were secured to warrant placing the matter before the voters.

HOQUIAM, WASH.—The City Council has entered into a contract with the Grays Harbor Railway & Light Company of Aberdeen for lighting the streets of the city for a period of five years. Under the terms of the contract the company is to install and maintain 220 incandescent lamps of 80 cp. In relocating lamps or placing new lamps the city is to bear the expense of erecting poles and stringing wires.

FOULSBRO, WASH.—The Puget Sound Pulp & Paper Company has been granted a franchise to erect and operate an electric transmission line in Foultsboro for a period of 25 years.

SEATTLE, WASH.—Plans are being prepared by the Puget Sound Traction, Light & Power Company for the construction of coal bunkers for its coal-pulverizing plant, at 1316 Western Avenue, to cost about \$17,000.

SEATTLE, WASH.—Plans have been submitted by A. H. Dimmock, city engineer, for the proposed elevated railroad to the shipyards. It is proposed to erect a timbered elevated roadway to extend from First Avenue South and Washington Street and West Waterst to Riverside, the shipyards and West Seattle.

SPOKANE, WASH.—The City Council has awarded the Washington Water Power Company a contract to install the new ornamental lighting system on Post Street from the east end of the Post Street bridge to the north side of Third Avenue, at \$40,545. The contract includes maintenance of lamps and furnishing electricity for same for a period of 10 years.

TACOMA, WASH.—Plans are being prepared by the electrical department for the construction of a substation to supply electricity from the municipal electric plant to operate the municipal tideflats car line.

REEDSPORT, ORE.—The Umpqua Power Company, recently incorporated, will take over the plant of the Gardiner Light & Power Company of Gardiner. The plant will be removed to Reedsport, but electrical service will be furnished in Gardiner. It is understood that the Umpqua Power Company and the Coos & Curley Telephone Company will erect a joint pole line.

BOVILL, IDAHO.—The installation of a storage battery in the municipal electric-light plant this summer is under consideration; also a third wire to cut out the street lamps at will, by the City Council. J. L. Shampine is engineer of power station.

NAMPA, IDAHO.—The City Council has awarded the Idaho Power Company a new contract under the terms of which the present arc-lighting system will be replaced with incandescent tungsten lamps. One hundred lamps varying in candlepower from 100 to 400 will be installed. At present there are 61 arc lamps.

HELPER, UTAH.—Application has been filed with the state engineer by G. R. Corey of Salt Lake City for permission to use 125 second ft. of water from Price River to develop 1600 electrical horsepower. The proposed plant will be located within a few miles of Helper. The plans provide for the construction of a concrete dam, 3 ft. high and 40 ft. long, the water to be carried in a ditch for a distance of 1½ miles, passing through two 4-ft. wheels under an 85-ft. head.

YUMA ARIZ.—Several additions and extensions are contemplated to the municipal electric-light, power and water plant: (1) The erection of an electric transmission line, 6600 volts, south and one to the west of town, at present to supply ranches nearby, and to be extended as demanded until they reach some nearby towns; (2) to extend the present secondary network to supply every part of the town, which will need about 1½ miles of line. It is possible that demand for electrical service on these new lines will make it necessary to install a new unit in the power plant. Bids have been received on a 50-hp. unit. Several petitions for street lamps in various parts of the town which are as yet unlighted are under consideration by the Council. Fred Kuecke is superintendent.

JOPLIN, MONT.—Sufficient signatures have been placed on a petition to practically insure the erection of an electric transmission line by the Montana Power Company to supply electricity in Joplin and other towns in this district.

DES MOINES, N. M.—The Village Trustees have decided to call an election to submit the proposal to issue \$50,000 in bonds to purchase the local electric-light plant and water works system and make extensions to same to the voters.

SANTA FE, N. M.—The first step has been taken by the City Council toward municipal ownership of the water and light plants. A committee has been appointed to place a valuation on the property of the company. The franchise of the Santa Fe Water & Light Company expires this year.

Canada

ARMAGH, ONT.—The Armagh Electric Company, it is reported, will ask for tenders for electrical equipment, to cost about \$49,000.

(Issued Feb. 19, 1918.)

1,257,100. ELECTRICAL FUSE; John H. Naylor, Everett, Mass. App. filed Nov. 17, 1913. Cartridge type.

1,257,106. ELECTRIC HEATING DEVICE; Leon F. Parkhurst, Pittsfield, Mass. App. filed July 23, 1911. Applies particularly to such as are provided with a flat heating surface and may either be used independently as stoves or heaters or in conjunction with other heating apparatus.

1,257,496—Lamp Cluster

- 1,257,117. AUTOMOBILE SIGNAL; Frederick Rauscher, Port Richmond, N. Y. App. filed May 27, 1916. Operable to indicate when there is a change in the direction.
- 1,257,155. IGNITION DEVICE; Harry R. Van Deventer, Sumter, S. C. App. filed Feb. 15, 1916. For internal-combustion engine.
- 1,257,163. ELECTRICAL BATTERY - CHARGING SYSTEM; Harry G. Webster, Chicago, Ill. App. filed April 18, 1912. Automobile.
- 1,257,177. DYNAMO - ELECTRIC MACHINE; Sven R. Bergman, Nahant, Mass. App. filed Oct. 13, 1915. Relates especially to direct-current dynamo-electric machines adapted for operation as motors and as generators of practically constant direct-current electromotive force when operating at variable speed.
- 1,257,178. DYNAMO - ELECTRIC MACHINE; Sven R. Bergman, Nahant, Mass. App. filed Oct. 18, 1915. Novel method of assembling parts of a dynamo-electric machine.
- 1,257,180. IMPULSE TRANSMITTER FOR AUTOMATIC TELEPHONE SYSTEMS; Gotthilf A. Betulander, Södertörns Villastad, Sweden. App. filed July 13, 1915. Consists in the use of a rotatable screw spindle for transmitting the rectilinear setting movement into a rotary movement.
- 1,257,193. WINDING FOR ELECTRIC MOTORS; Neil Currie, Jr., Pittsfield, Mass. App. filed March 4, 1916. Improved winding.
- 1,257,246. MAGNETIC SHUNT; Lloyd M. Killgore, Pittsfield, Mass. App. filed Jan. 29, 1917. Each magnetic shunt is composed of a number of pieces of magnetic material, the number of which may be readily varied after the complete assembly of the transformer.
- 1,257,255. ELECTRIC SWITCH FOR MINES; Edward Leach, Rathmel, Pa. App. filed April 12, 1917. Automatic cut-out switch for use in connection with line and trolley wires.
- 1,257,272. ELECTRIC-RESISTANCE ELEMENT; Guy M. Laird, Chicago, Ill. App. filed May 19, 1916. Composed of a metal which shall have the property of being particularly low in electric conductivity, have a melting point exceeding that of pure copper, and be capable of resisting oxidation at all temperatures and under all conditions to which it needs to be subjected, while at the same time possessing characteristics permitting it to be drawn or otherwise worked to form strips, strands or filaments.
- 1,257,283. AUTOMATIC TELEPHONE SYSTEM; Alfred H. Dyson, Chicago, Ill. App. filed Aug. 19, 1907. Novel arrangement of electrical connections between the switches whereby the chances of the calling line finding an idle trunk through which to extend its circuits are greatly increased.
- 1,257,287. SWITCH DEVICE; William Kaisling, Chicago, Ill. App. filed June 5, 1914. Plurality of plungers are used, some of which are adapted for individual service and some of which are adapted for alternate service.
- 1,257,289. METER PANEL; Hubert F. Krantz, Brooklyn, N. Y. App. filed Dec. 18, 1912. Each busbar of panel can be connected to the same branch circuit.
- 1,257,294. AUTOMOBILE TURNING SIGNAL; Henry Patrick, New Brunswick, N. J. App. filed March 23, 1917. Improvements.

Record of Electrical Patents

Notes on United States Patents

(Issued Feb. 26, 1918.)

- 14,136. (REISSUE.) PROCESS FOR THE ELECTROLYSIS AND TREATMENT OF SULPHATE LIQUORS; App. filed Aug. 18, 1914. Improved process.
- 1,257,303. REPEATER SYSTEM; John H. Bell, East Orange, N. J. App. filed May 16, 1916. Simplifies the arrangement of repeater circuits.
- 1,257,312. ALKALINE - BATTERY PLATE; Campbell C. Carpenter, Niagara Falls, N. Y. App. filed Oct. 18, 1912. Adapted to withstand the expansion and contraction during the repeated charge and discharge.
- 1,257,317. TELEPHONE-EXCHANGE SYSTEM; Henry P. Clausen, Mount Vernon, N. Y. App. filed Oct. 12, 1915. Improvements in telephone trunk circuits.
- 1,257,336. SAFETY DEVICE FOR ELEVATORS; Alexander Gagnon, Bideford, Me. App. filed Nov. 8, 1916. Means for automatically bringing the elevator car to a stop.
- 1,257,338. LINE SWITCH; Charles L. Goodrum, New York, N. Y. App. filed Jan. 20, 1916. Relates to automatic telephone systems.
- 1,257,339. FLEXIBLE ELECTRIC HEATER; Albert E. Grapp, Minneapolis, Minn. App. filed Dec. 20, 1915. Adapted for use for warming up various parts of an internal-combustion engine.
- 1,257,349. CONTROL SYSTEM; Rudolf E. Hullmund, Pittsburgh, Pa. App. filed Jan. 6, 1916. Single-phase commutator motor for starting a phase converter.
- 1,257,356. ALUMINOUS COMPOSITION AND METHOD OF PREPARING THE SAME; Otis Hutchins, Niagara Falls, N. Y. App. filed Nov. 14, 1917. Electric furnace process.
- 1,257,361. TELEPHONE-EXCHANGE SYSTEM; Charles W. Keckler, Newark, N. J. App. filed April 24, 1917. Central-energy type; provides improved signaling means.
- 1,257,362. TELEPHONE-EXCHANGE SYSTEM; Charles W. Keckler, Newark, N. J. App. filed April 24, 1917. Battery type; provides improved signaling means.
- 1,257,370. TELEPHONE-EXCHANGE SYSTEM; Alben E. Lundell and Franklin A. Steers, New York, N. Y. App. filed Oct. 26, 1916. Operator is informed that a calling subscriber desires her attention.
- 1,257,375. HOUSING ELECTRIC APPARATUS; Aldah R. Mecham, Oklahoma City, Okla. App. filed March 18, 1916. Moisture-tight.
- 1,257,381. LOW-FREQUENCY-SIGNAL REPEATER; Harold W. Nichols, Maplewood, N. J. App. filed Sept. 24, 1915. Amplifies and repeats low-frequency currents.
- 1,257,382. INDIRECT ILLUMINATION; Henry G. O'Neill and Ward E. Pearson, New York, N. Y. App. filed Oct. 30, 1916. Arrangement of indirect or reflected electric or other light rays with a mirror.
- 1,257,392. TELEPHONE - LINE - SELECTING SYSTEM; Frank N. Reeves and Alben E. Lundell, Newark, N. J. App. filed April 16, 1915. Improvements.
- 1,257,391. TERMINAL BANK; John N. Reynolds, Greenwich, Conn. App. filed Sept. 17, 1915. Inductive action prevented.
- 1,257,396. PROCESS OF MAKING METALLIC CATALYZERS; William D. Richardson, Chicago, Ill. App. filed Nov. 11, 1912. New method of preparing highly reactive catalysts.
- 1,257,412. TRAIN - DISPATCHING SYSTEM; Paul J. Simmen, Indianapolis, Ind. App. filed Nov. 18, 1911. Improved system.
- 1,257,418. REFILLABLE FUSE; Basil L. Spurr and Frank A. Tittmore, Richmond, Cal. App. filed April 27, 1916. Fusible element of the proper capacity only may be installed.
- 1,257,426. VOLTAGE - REGULATING SYSTEM FOR VAPOR RECTIFIERS; William Tschudy, Wilkinsburg, and Sidney W. Farnsworth, Pittsburgh, Pa. App. filed Feb. 19, 1914. Means for regulating the voltage in the direct-current circuit.

- 1,257,440. ELECTRICAL BURGULAR ALARM; Alfred Zehden, Berlin, Germany. App. filed March 18, 1914. Resistance connected as branch of Wheatstone bridge.
- 1,257,451. PROTECTION OF ELECTRIC CABLES; John H. Bowden, London, and Harry E. J. Thompson, Battersea Park, London, England. App. filed March 15, 1916. Protection of electric cables against leakage and faults in the insulation.
- 1,257,463. SWITCH; William D. Dean, Chicago, Ill. App. filed June 2, 1913. Simple and efficient arrangement of parts.
- 1,257,468. INTERNAL - COMBUSTION - ENGINE TESTING DEVICE; Roy G. Edgerton, Suffolk, Va. App. filed March 31, 1917. Readily applied to or removed from the cylinders.
- 1,257,496. LAMP CLUSTER; George L. Lamb, Nappanee, Ind. App. filed April 16, 1917. Adjustable lamp socket.
- 1,257,514. ELECTRICAL MEASURING INSTRUMENT; William Meyer, Chicago, Ill. App. filed Aug. 23, 1915. Double-scale instrument.
- 1,257,516. INSULATOR ASSEMBLY FOR ELECTRICAL CONSTRUCTION; Earle A. Muckey, San Francisco, Cal. App. filed Aug. 23, 1917. Universal detachable rigid connection.
- 1,257,526. CONSTANT-PRESSURE SOLID RECTIFIER; Greenleaf Whittier Pickard, Amesbury, Mass. App. filed Sept. 15, 1909. Improvements.
- 1,257,531. PROCESS FOR MAKING CATALYZERS; William D. Richardson. App. filed Nov. 11, 1912. Improved method of hydrogenating oils or fats to harden or solidify them.
- 1,257,533. ELECTRIC SWITCH; Joseph Sachs, Hartford, Conn. App. filed Feb. 18, 1915. Used in conjunction with electromagnetic actuating mechanism.
- 1,257,534. SWITCH; Joseph Sachs, Hartford, Conn. App. filed April 17, 1915. Pendant snap switch.
- 1,257,555. METHOD OF PRODUCING ANALGESIA; Frederick K. Vreeland, Montclair, N. J. App. filed June 25, 1914. By means of electric currents.
- 1,257,596. POCKET HAND-LAMP; Joseph C. Ford, Madison, Wis. App. filed May 17, 1917. A switch for connecting the battery and the electric bulb, located between the two.
- 1,257,599. ELECTRIC HEATER; William S. Hadaway, Jr., New York, N. Y. App. filed Sept. 5, 1911. Electric heating element is embedded in the device.
- 1,257,615. METHOD AND MEANS FOR ELECTRICALLY WELDING THE RIMS FOR FLANGES OF WHEEL OR CYCLE TIRES

1,257,514—Electrical Measuring Instrument

- Rudolf Kronenberg, Ohligs, Germany. App. filed Sept. 20, 1917. Full uniformity of welding.
- 1,257,618. ELECTRIC LIGHTING SYSTEM FOR AUTOMOBILES; Dominick F. Leone, Seattle, Wash. App. filed May 17, 1917. Improved controller and electrical connections.
- 1,257,646. AUTOMOBILE SIGNAL; Thomas E. Smith, Los Angeles, Cal. App. filed Jan. 8, 1917. Indicates the direction in which the automobile is to turn.
- 1,257,651. LINE-TESTING INSTRUMENT; Oscar F. Tallman and Fred E. Hubert, St. Louis, Mo. App. filed July 20, 1914. Compact and easily transportable.

Number 13

Support the Third Liberty Loan

TO WIN the war each of us must feel down deep in the innermost recesses of his heart a firm conviction of its righteousness. If as individuals we are not called on to shoulder a gun or to render some distinct personal service to the nation, we must be conscious of our obligation to support and sustain those who are. Above all, we must never lag in our zeal for the cause, but instead strive incessantly to create a sentiment which will cheer, inspire and keep flaming the light of courage and hope in those who face the foe. With this issue of the ELECTRICAL WORLD we distribute a colored cartoon showing how all may assist in the triumph of free democracy over ruthless autocracy. Consider the ample security back of the Liberty loan, think of the power of your investment to help in making the world safe, and buy your share of the bonds.

The Eternal Labor Problem in Industry

THERE has never been a time within the memory of living men when the labor question, involving all the intricate relations between the worker and the capitalist and the cost of living, has been so acute as at present. The situation, growing more critical for some years, has been aggravated by the world war to an unparalleled degree. The papers by L. K. Comstock published in the ELECTRICAL WORLD of March 16 and 23 give a striking analysis of the situation and suggest at least a possible remedy.

The long and short of the whole situation is, first, that we are going through a period of monetary inflation, complicated by the growth of a somewhat cumbersome industrial system in itself tending to needlessly increased costs of every kind; second, there has been superimposed on this the startling changes in demand and supply enforced by the conditions of war. We lay aside for the present the more or less theoretical factor involved in gold production, which has not been without its effect, but which is in only minor degree chargeable with the immediate situation.

For a good many years past those industries which have to do with the fundamental necessities of life have been gradually assuming a more and more complex development. It is a matter of common knowledge that in many of the commodities concerned there has been careful and thorough systematization of production and distribution for the purpose of controlling what would otherwise be the normal flow of supply and demand. Many commodities have been practically controlled in

their entirety by what are virtually trusts. The operations of these have been repeatedly disclosed, and they are in fact apparently well known to everybody except those whose official duty lies in the line of regulating them.

Their fundamental principle is by getting possession of large quantities of necessary articles to create at will shortage and surplusage which take the place of the ordinary supply and demand resting on the principle of an open market. When a shortage, real or artificial, is created in the supply of any article its price shoots upward, very rapidly at first, afterward more gradually, as rising prices forcibly curtail consumption. When there is a surplus prices fall, but at a much slower rate, forming a sort of hysteretic loop, the area of which represents in the main the profit of those who manipulate the market. The variation of price with shortage and surplus was actually worked out by an English investigator for wheat some years ago, but it has never been thoroughly studied for commodities in general under the control of single or closely allied bodies.

Added to this has been the effect of speculation pure and simple and an increasing complication of the whole matter of industrial distribution involving a long chain of intermediaries between those who produce and those who consume, all of them taking toll as the product goes by. The net result of these factors has been the startling rise in the cost of necessities to which Mr. Comstock directs attention. The effect has been to send up living costs, as he shows, out of all proportion to the rise in wages during the same period, and the attempt on the part of the wage earner to equalize conditions has resulted in very grave disturbances which are now rapidly becoming worse. Just at present the inflation due to the war is still further accentuating the difficulty. The huge loans negotiated both here and abroad have added to the inflation by a species of pyramiding, differing from country to country but producing the same effect, and the government in spending enormous sums under contracts which give every incentive to lavish expenditure has made a bad matter worse.

Broadly, the trouble with the situation is the lack of following the fundamental principles of righteousness, and the remedy, in so far as there is one, is to carry out the gospel of the square deal. Both workmen and manufacturer are at fault, since human nature is the same in both classes. On the one side is a frantic effort to keep down the labor cost of production, since the cost of materials cannot at present be kept down. On the other hand, there is the determination to get for labor as large a proportion as practicable of the

rapidly increasing profits of industry. The late James M. Dodge, a most patient and sympathetic student of the earlier phases of the situation, used to say that he felt it to be his duty to see to it that his workmen got a comfortable living wage at all times, and that he had found that in thus helping them they helped him in at least equal measure. Many another manufacturer takes the same enlightened view of the situation, but it is not yet sufficiently general to remedy the situation in hand.

Mr. Comstock's view of the matter is that it might be possible to effect by suitable regulation an automatic readjustment of wages at stated intervals, say semi-annually, based practically on maintaining wages and the cost of fundamental commodities on an even basis. Whether this could be carried out practically is not easy to determine, but it is, as a matter of fact, a process which is going on spontaneously, irregularly, and with rather disastrous results to the continuity of production. Perhaps Mr. Schwab is right in saying that by the end of the present conflict the workingman will be on the top of the heap. But, however this may be, it is certain that the classes which suffer most acutely are those with relatively fixed incomes, whether in the form of salaries or dividends. They are ground between the upper and the nether millstone, and no solution of the problem can be considered sound which does not take them into account.

Practically the present situation is disastrous in that it so greatly reduces the effectiveness of the American dollar in carrying on the war as to make the boasted wealth of the country of much less avail than we fondly supposed. These are times of enormously rapid changes, financially and socially, and the need of co-ordinating them and in so far as possible of regulating them is fundamental. It is the biggest task that lies before the government and its citizens in a period of prodigious efforts.

Safe Design for Switching Apparatus

THOSE of our readers who have to do with station operation will find much of interest in the paper by M. M. Samuels and F. N. Bechoff in the current issue. It takes up fundamentally the questions of switchboard design and operation with respect to safe and convenient working. All large stations nowadays have to depend to a very considerable extent on remote control. The fundamental points in planning a necessarily somewhat intricate system are to see that the switch controls are as easy as possible to handle and interlocked so that a necessary sequence of operations cannot be performed in the wrong order. One very useful suggestion is that control switches should have such conspicuous mechanical indicators, aside from all control lamps, as to show the last step taken by the operator and impress it upon him. Control lamps alone may lead to confusion. Another capital hint is that there are cases in which a little complication, like the necessary use of both hands, which the switchboard operator has to think about for a moment may prevent his doing the wrong thing in an emergency.

We note with pleasure the opinion expressed by the authors that most oil circuit-breaker compartments are too small and somewhat inaccessible. In a great

many stations an obsession of compactness has ruled switchboard design, and while in itself compactness is a good thing structurally, it has very often led to insufficient space, particularly between high-tension apparatus, leading both to danger to the operator and to considerable risk of involving a large amount of apparatus in a single accident which might otherwise have been trivial. It must be remembered that, particularly in a high-tension station, even apparently unimportant pieces of apparatus may be the source of very serious trouble, as when a whole station was put temporarily out of service because an inquisitive rat short-circuited a potential transformer. It may not be necessary to paint all high-tension wiring and connections red, but they always should be either so marked or so placed that there can be no possible mistake as to their character. The designing engineer will find the paper under discussion full of interesting hints, and its study will amply repay him.

The Working Temperature of Generators

IN THE good old times before generator design had been placed on a really scientific basis the heat limit as the ultimate index of capacity was somewhat neglected. Little was known of what the heating conditions really were, and still less of the distribution of temperatures throughout the structure, which in the last resort determines whether insulation is reliable or will break down. "Nigger on the core" was a common acquaintance.

In the current issue H. D. Stephens gives a very illuminating account of some of the recent methods which have been adopted to measure and keep track of the temperatures within the structure so that the approach of danger may be scented without smelling the insulation. The hottest spot in an armature rather than the average temperature is the thing to be sought, and while in small machines with shallow windings a thermometric method gave a useful approximation, it soon had to be abandoned, and the next step in advance was resistance measurement. But this was merely an average and could not give the necessary information regarding the approach to the danger limit.

Nowadays big generators are customarily built with telltales placed, as nearly as judgment and experience can indicate, at the hottest points in the winding. These have taken the form of exploring coils embedded in the winding, and of which the resistance can be quickly noted, or of thermocouples used in the same way. The indicating apparatus of either kind can be graduated in actual temperature, so that the rise of heating toward the danger point can be accurately followed and noted.

Mr. Stephens describes particularly the most recent form of thermo-electric detector, very convenient on account of its small bulk, which enables it to be readily embedded in the windings, and its combination of mechanical strength and sensitiveness. Both coils and thermocouples enable the operator to watch closely the performance of the generators during the time of heavy load and give very valuable information regarding failures of ventilation which may be due to the choking of the air passages and must be met by a thorough cleaning.

Thus far such apparatus has not been readily applicable to the revolving fields of alternating-current machines or the revolving armatures of direct-current machines, on account of the difficulties interposed by the moving contacts. The next step would seem to be to conquer these particular troubles so as to give the same valuable information regarding the moving parts which is now available with respect to the fixed ones. The difficulties are considerable, but probably not insurmountable, and the resourceful inventor has here a fine field for his activities.

Specifications for Factory Lighting

FOLLOWING up Professor Clewell's consideration of some of the changes in factory lighting comes his study of the changes embodied or proposed in some of the state codes. Leaving aside the questions of emergency and entrance lighting, the chief points in any such code are those regulating the intensity of the illumination, together with provisions for the elimination of glare and suitable distribution of light. Now, these three together make up the problem of the illuminating engineer in industrial lighting. If they could be really embodied in a code, the whole technique of illumination could be reduced to hard and fast formulas. Hence comes the difficulty of drawing suitable codes and particularly of drawing them so that they can be enforced.

In provisions for intensity of illumination the fundamental thing is the classification of work so that the requirements of the case in hand will be readily understood. Here is the main difficulty. While it is possible to generalize within reasonable limits of error, it is very difficult to make a sound classification which shall cover all the phases even of any particular kind of manufacture. As Professor Clewell notes, the proposed Ohio code attempts to classify under six main heads some 250 kinds of work. This lays too much stress on the mere matter of intensity and gives little information as to the other requirements of any particular situation, such as distribution of light and glare, which are at least equally important with intensity in determining the effectiveness of artificial lighting.

No specification with respect to glare has yet been devised which is of very much practical use. So much depends on the nature of the work and the situation of the machinery that generalizations are very unsafe. The best that can be done is to give sound advice and to leave its application to the expert on the spot. The mere question of reflecting surfaces on the work will go far toward determining the maximum permissible ap-

parent brilliancy of the source and its best location.

Looking at Professor Clewell's tabulation of the situation, the striking feature which at once presents itself is the upward tendency in the general level of illumination. The real economic question is, not how little light one can get along with, but how much can be applied advantageously toward the increase in the quantity and quality of the work.

Much of the burden of enforcing codes will rest on the state inspectors, who in the discharge of this duty ought to be particularly well informed concerning the methods of modern illumination. Wide-awake manufacturers in equipping their plants very commonly call in experts on lighting, and when this is done the inspector will find no infraction of the code. The inspectors' troubles arise when dealing with those who have not taken this wise precaution, and they ought to know enough of the art to steer them, at least, in the right direction. It would be a good thing if the Illuminating Engineering Society could take some suitable opportunity for instructional work with special reference to the needs of inspectors in enforcing the law. It would be no very difficult matter to provide a series of demonstrations which would impress most forcefully the fundamentals of factory lighting and tend strongly to higher standards of efficiency.

A Central-Station Pioneer, A. C. Dunham

THE death of Austin C. Dunham, former president of the Hartford (Conn.) Electric Light Company and one of the pioneers of central-station progress in this country, as reported in last week's issue, removes a historic figure closely identified with early central-station development. After the election of Mr. Dunham as president of the Hartford company in 1882 there followed year after year of brilliant development work in centralized electrical supply, embodied in such advances as polyphase transmission from water power, the use of alternating-current, inclosed-arc lamps, 60-cycle rotary converters, the constant-current, alternating-current arc-lighting system, the first steam-turbine application, the initial try-out of the Nernst lamp in commercial service, the installation of the first storage battery in central-station service, first tungsten street lamps, and epochal work along electric cooking and flat-rate residential lighting lines. Mr. Dunham was one of the first to appreciate the economies of energy production by high-powered steam turbines as compared with water powers of ordinary character. He carried his directors with him far beyond the conventional paths of every-day practice.

AS AN indication of the broad scope of the engineering subjects that the **ELECTRICAL WORLD** discusses each week, the following, which will be dealt with in early issues, may be mentioned: A technical discussion regarding investigations to determine methods of improving the starting qualities of synchronous motors; the concluding section of an article regarding the New Bedford (Mass.) generating station; specific examples of installations that have been converted from coal-burning to

The Coming Issues

oil-burning plants, with some operating results; an article by a central-station engineer telling how to obtain the proper protective action from transformer fuses without depreciating service; features of an outdoor substation, and some interesting details regarding a large hydroelectric development in Canada. The usual compilation of monthly central-station statistics, now in course of preparation for publication, receives added interest from the extraordinary war-time influences affecting it.

Safety Features in Switching Apparatus

A Compilation of Some Ideas That Have Been Developed for Ready Reference of Electrical Engineers in Designing or Remodeling Switching Installations

BY M. M. SAMUELS AND F. N. BECHOFF

WHILE in small installations it was generally possible for one switchboard operator to handle the entire switching equipment of the station, it has become necessary in large, modern, high-voltage stations, where the switching apparatus very often occupies several floors, to depend not only on assistant operators and helpers but principally upon electrical signaling and indicating devices. A great many ingenious and useful safety devices and schemes of connections have been devised within recent years, but the development of large-size and higher-voltage apparatus has been so overwhelmingly rapid that very often old and thoroughly experienced station operators find it difficult to keep in touch with them. Even though the designing engineer is familiar with all of them, he may easily forget to include one or more essential safety features in his design.

It is therefore the purpose of this article not so much to exhaust the whole field of safety engineering as to bring out in systematic form some of the well-known safety features and at the same time call attention to some which are less known but which are nevertheless of great importance. It is hoped that other contributors will in the future make additional suggestions so that by and by the designing engineer as well as the operator will have ready references whenever he requires them.

The design of control switches is one of the first things that demand attention, since switching apparatus used in modern power houses is usually installed remote from the switchboard and operated electrically therefrom by means of small control switches. To

and ready to perform safely the next operation. Poor contacts and hidden springs should therefore be eliminated. The usual method of indicating by means of colored lamps whether a circuit is open or closed is not sufficient for modern installations where it is possible not only for a circuit to open automatically but to be opened from other points' either inside or outside of the power house. The lamp indicates only that the circuit breaker is open but does not indicate whether the circuit was opened by the operator himself. It is therefore essential that the control switch should be equipped with a reliable, prominent and easily distinguishable mechanical indicator which will indicate the last operation performed by the operator himself. There are some switches now on the market which meet these requirements.

With the great number of indicating lamps on modern switchboards, it is preferable in order to avoid confusion to have the two lamps of a control circuit together with the respective name-plates on a common escutcheon plate with the control switch. It should further be possible to lock the control switch so that it cannot be operated whenever any repairing or inspection is being done on the apparatus controlled by it. Push switches should not be used except in cases where they could not possibly be operated accidentally by the operator's elbow or knee.

To avoid the possibility of closing a main generator circuit breaker without first going through the necessary process of synchronizing, it is customary to interlock the closing circuit of the circuit breaker with the synchronizing receptacle, so that the synchronizing plug

FIGS. 1 AND 2—THREE-WAY AUXILIARY PUSH-BUTTON INTERLOCKED WITH THREE-WAY AUXILIARY SWITCH FOR RESET-
TING BELL ALARM; METHOD OF CONNECTING DANGER SIGNALS
ALONG A HIGH-TENSION BUS

satisfy the majority of switchboard operators a control switch should be as easy to handle as possible and should be so constructed that the operator cannot perform the wrong operation. These requirements should be obvious, since it is very often necessary to open a circuit hurriedly without having any time for reflection. The switch should always be in working condition

FIGS. 3 AND 4—FAILURE TO OPEN DISCONNECTING SWITCH
MAY ENDANGER PERSON WORKING NEAR OIL-SWITCH TERM-
INAL; SIGNALS AT OIL SWITCH INDICATE WHETHER DIS-
CONNECTING SWITCH IS OPEN OR CLOSED

must be inserted before the circuit breaker can be closed, as shown in Fig. 5.

A system of control connections like that shown in Fig. 6 is still to be found in a good many installations.

¹For instance, it is possible in some of the modern railway systems to trip a circuit breaker in the station from various points along the track.

This method, although it employs a small number of wires between the switchboard and the circuit breaker, must be condemned from a safety point of view since it may happen, when a circuit breaker is being repaired, that an accidental short circuit across the green lamp, even with the control switch locked, would energize the closing coil and thus close the breaker and injure the

flashes. In this connection it may be suggested that it would be a great step toward safety if all lever switches, particularly those on 500-volt circuits, were similarly mounted on the rear of the panels. Carbon-break circuit breakers mounted on the front of the board should be so placed that they cannot strike a person standing near when they open automatically.

FIGS. 5, 6, 7 AND 8—METHOD OF INTERLOCKING OIL-SWITCH CONTROL CIRCUIT WITH SYNCHRONIZING CIRCUIT; THREE-WIRE AND FOUR-WIRE CONTROL CIRCUITS (THE THREE-WIRE ARRANGEMENT HAS ITS DISADVANTAGES); PUSH-BUTTON IN FIELD-CONTROL CIRCUIT TO AVOID ACCIDENTAL OPENING OF FIELD

operator. The scheme of connections shown in Fig. 7 is therefore to be recommended as far safer. The fact that with this scheme the red lamp is in series with the trip coil cannot be considered harmful, since a short circuit across the red lamp would only open the breaker. There is an additional advantage with this scheme, which is that any injury to the tripping circuit while the circuit breaker is closed will be called to the operator's attention on the switchboard by the automatic extinguishing of the red lamp. Thus the operator can always be certain that the tripping circuit is in good working order.

Whenever a field circuit breaker of a large unit is electrically operated by means of a control switch care should be taken that the operator does not open the field accidentally or hastily. In order to force the operator to give the matter a second thought before opening the field it is advisable to insert a normally open push-button in series with the opening side of the control switch, so that to open the field both hands must be used. This arrangement is shown diagrammatically in Fig. 8.²

All bell-alarm relays and other bell-operating devices should be so arranged that the bell continues ringing until stopped by the operator. However, whenever so stopped it should automatically reset itself and be ready for the next operation. A three-way auxiliary switch on the circuit breaker in connection with a three-way snap switch, as shown in Fig. 1, is often used for such purposes. The alarms for the various types of circuit breakers should be made distinguishable by using bells, horns or whistles having different sounds to indicate the automatic opening of different types of apparatus.

The field switch for small units, mounted on the switchboard itself, should not be placed on the front but on the rear of the panel, with an insulated operating handle on the front to avoid accident through

Double-throw switches, if not mounted horizontally, should be equipped with locks or steps to prevent accidental closing.

Fuses of heavy capacity should not be used in power stations at all, not only on account of their unreliability but also on account of the great expense of their maintenance. Automatic devices should be used instead. If fuses are used they should be of the inclosed type only and should be placed on the rear of the switchboard.

Care should be taken to allow for liberal passageways behind all switchboards. A mistake is often made

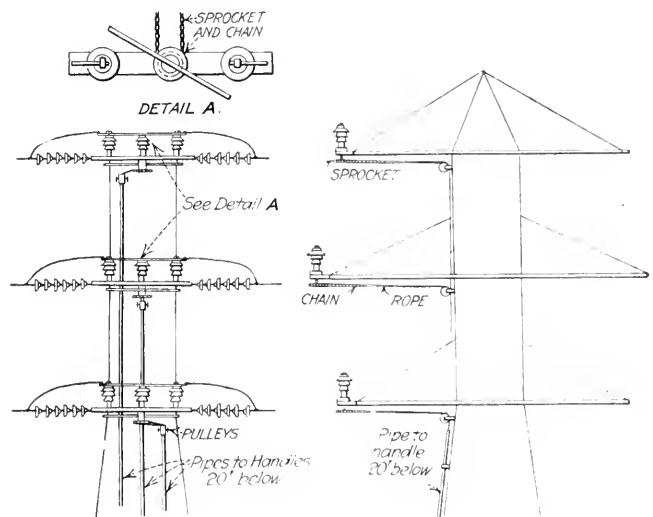

FIG. 9—70,000-VOLT LINE DISCONNECTING SWITCHES ON TRANSMISSION-LINE TOWER OPERATED BY MECHANISM INSTEAD OF BY SWITCH HOOK

by providing a certain distance from the back of the panels to the wall without regard to the fact that many pieces of apparatus project a considerable distance to the rear of the board, thus materially reducing the size of the passageway. The idea of insulating the switchboard frame must be considered altogether obso-

²By courtesy of C. O. von Dannenberg.

lete, and all switchboard framework should be grounded, this being by far the safer method.

Whenever oil switches are mounted directly on the switchboard provision should be made to catch the oil in case of a leak in the tank in order to avoid oily and slippery floors around the switchboards. Buses and connections within reach should be inclosed in grill-

FIGS. 10 AND 11—TWO METHODS OF MOUNTING BUSBARS, THE FIRST BEING PREFERABLE

work, and in cases where a craneway exists over the switchboard protecting covering should also be installed above the switchboard to protect it from anything which may accidentally fall from the crane.

Switchboard illumination is still a much neglected matter. For average switchboard heights 90-in. (228.6-cm.) shades, similar to Benjamin No. 5525, spaced approximately 5 ft. (1.5 m.) in front of board and 1 ft. (0.3 m.) above its top, will be found to give satisfactory results in most cases.

All modern control switchboards should be equipped with mimic bars between all control switches to indicate the interconnections between circuits. Such mimic bus arrangements should be made as simple as possible, and all control switches should be arranged with due regard to a simple layout of the mimic buses.

A great deal of information on the subject of bus and oil circuit-breaker compartments was presented in a previous article published in this paper.³ If more attention had been paid to the suggestions made therein, some of the awkward bus arrangements which have recently come to the writer's attention could have been avoided. A few additional remarks on this subject will therefore not be out of place.

All openings in the bus structure opposite bus supports as well as those in front of bus sectionalizing switches should be closed, preferably by wire-glass doors, which will prevent accidental contact with live parts and at the same time allow for frequent inspection. Such doors should preferably be equipped with locks.

The arrangement shown in Fig. 10 is to be preferred to that shown in Fig. 11 because the former allows complete inclosure of the buses without leaving any openings and at the same time gives greater accessibility to the bars. It also makes it easier to arrange the bus laminations in vertical planes, which gives better cooling. In Fig. 11, where the insulator is mounted on the concrete slab, the slab must be reinforced with iron, which is often the cause of heating, while in Fig. 10 no reinforcing is required.

Compartment doors in front of oil circuit breakers or fuses should be so constructed that they can swing

out in case of an explosion. On the other hand, doors in front of compartments containing apparatus not subject to explosion should be rigidly fastened. Hinged doors are to be preferred to removable doors, first, because the operator may forget to replace a removable door, thus leaving the compartment open; second, because a removable door is not adapted for locking, and, third, because a removable door if mounted at a considerable height may injure the operator while he is removing it. For compartments containing apparatus of high rating the doors should be provided with openings for ventilation purposes. Hinged doors can be grounded, therefore there is no argument against the use of either all-metal or part-metal doors. In some stations the doors are so interlocked with the circuit-breaker mechanism that they cannot be opened unless the circuit breaker is open. This arrangement, although seemingly offering features of safety, has been found in many cases not to fulfill the requirements for which it was intended, since such interlocks are necessarily complicated and often prevent the door from being opened altogether when it is necessary to open it hurriedly.

Generally it may be stated that the majority of oil circuit-breaker compartments are designed too small and are therefore inaccessible. Oil circuit breakers and mechanisms should be designed so that at least a 4-in. (10.1-cm.) brick wall can be built between phases and still leave ample handling space in the compartments for wiring inspection, repairing and removal of the oil tanks, particularly for cases where a single oil tank is used for multiple circuit breakers. Even in cases where tank lifters are provided there is often hardly room enough for properly attaching the lifter to the tanks.

For very long runs of busbars there should be lamps at certain intervals to indicate whether the bus is "alive" or not, a red lamp indicating danger and a green lamp indicating that the bus is "dead." A simple method for signals of this sort is shown in Fig. 2, where a potential transformer connected across the bus directly operates the red lamp, while the green lamp is supplied from an independent source of energy and

FIG. 12—SIX 2000-AMP. DISCONNECTING SWITCHES IN COMPARTMENTS OPERATED BY ONE MECHANISM

is put in circuit by a no-voltage relay on the potential transformer. A green lamp alone would not give sufficient indication that the bus is dead, since an accidental interruption of the potential transformer circuit, either through a short circuit in its winding or other causes, would cause the green lamp to light up even though the bus were alive. When both lamps are used

³ELECTRICAL WORLD, Jan. 15, 1916.

the operator will know that the bus is "dead" only when the red lamp is out and the green lamp is on. In such cases potential transformers should be connected to the buses without fuses, as is done in the case of potential transformers on voltage regulators.

Where disconnecting switches are operated by switch hooks they should be equipped with locks to prevent their accidental opening. Such locks should be arranged so that the switch hook cannot be removed unless the switch is either entirely open or entirely closed and locked. However, it seems that the time is ripe for the complete elimination of the switch hook, which has ever been a source of danger to operator and apparatus. It is possible to arrange disconnecting switches in such a way that they can be operated safely by means of a mechanism. On high-tension work, transmission lines as well as outdoor stations, the strain-insulator type of disconnecting switch has unfortunately been popular. For the operation of such switches, which are generally mounted very high, sometimes as much as 70 ft. or 80 ft. (about 23 m.) above the ground, it is necessary to provide operating platforms. The operator is forced to stand on such platforms and reach up to the switch with a stick which sometimes must be as long as 20 ft. (6 m.). Not only does it take a considerable length of time to clear a line in this manner, but when swinging the long switch hook the operator will often break insulators and other apparatus. Furthermore, there are cases on record where because of a heavy wind an operator was thrown off the platform and killed. Line disconnecting switches with operating mechanism can even be arranged on transmission towers.

An arrangement whereby the disconnecting switches are mounted on the ends of the cross-arms of a 70,000-volt transmission-line tower of popular form is shown in Fig. 9.⁴ It was not even necessary to make any changes in the design of the cross-arms. A chain mechanism is used, the chain running vertically, mostly in pipe, to prevent entanglement during wind. However, a simple pipe mechanism can also be devised to serve the purpose.

Where disconnecting switches are mounted in compartments it should be possible to open the disconnecting switch before opening the compartment door for reasons of safety. This, of course, is impossible when the switches are operated by means of a switch hook, but becomes feasible when the operation is performed by a mechanism, since an operating handle can be placed outside of the compartment. Switch hooks are often mislaid or even broken, and even when the switch hook is at hand it takes a considerable length of time to open six disconnecting switches, which must be done in the majority of cases to clear one circuit breaker. With a mechanism (see Fig. 12)⁴ all six disconnecting switches can be opened at once.

Where instrument transformers which are connected in series with oil circuit breakers have to be calibrated or repaired the operators sometimes open the oil switch, which of course "kills" the instrument transformer even if the disconnecting switch is closed (see Fig. 3). There are cases on record where an operator, after finishing his work, in attempting to descend from the common foundation of the oil circuit breaker and instrument transformer, accidentally reached over

to the live side of the oil circuit breaker and was killed. For this reason it might be advisable to have a warning signal at the oil circuit breaker to tell the operator that the disconnecting switch is closed. Such a signal cannot be provided easily where disconnecting switches are operated by switch hooks. However, where the disconnecting switches are operated by some mechanism it is a very simple matter to install an auxiliary switch which would light a red lamp at the oil circuit breaker when the disconnecting switch is closed and a green lamp when it is open (see Fig. 4). Such auxiliary switches can also operate red and green lamps on the switchboard panels in similar manner.

As an additional precaution, a multi-tumbler lock might be installed on the disconnecting switch handle to lock it in the closed position, so that nobody could accidentally open the disconnecting switch under load. It could also be locked in the open position, so that nobody could close the disconnecting switch when repairing or inspection is being done on the oil circuit breaker. Of course, better results could be obtained with electrically operated disconnecting switches, either by motor or solenoid, and where the extra expense is warranted electrical operation from the switchboard should be used. With this arrangement it is, of course, possible to go a step further and interlock the control circuits of the oil circuit breaker and the disconnecting switches.

Disconnecting switches should be so placed that the blade is dead when the switch is open. This is not always possible when using hook-operated switches but is possible in every case when the disconnecting switches are operated by a mechanism as shown in Fig. 12.

An Old Dynamo Redivivus

This photograph was taken recently at Bagdad, Fla., as the machine shown was being hauled to Bay Point, Fla. It illustrates that every machine and every known

OLD TIMES COME BACK

means of transportation is being brought into service. Things laid away for years must go to work again to help meet the demands. The machine in the picture is now furnishing light at a plant where submarine chasers are being built. This dynamo was out of service for many years, but like the team of oxen it has been put to work again.

Harmonics in Symmetrical M-Phase Systems*

A Consideration of Conditions Which Can Exist in Star-Connected or Mesh-Connected Systems Having Any Number of Phases, with a General Discussion of Mmfs. in Which Harmonics Are Present

BY V. KARAPETOFF

Professor of Electrical Engineering, Cornell University

SINCE more than three phases are occasionally employed in practice (for example, six-phase and twelve-phase combinations) it seems that the time is ripe for a general treatment of higher harmonics in any symmetrical m -phase system; that is, one in which the induced sinusoidal voltages are displaced from one another in time phase by an angle $2\pi/m$. Higher harmonics in the three-phase system have been treated extensively in electrical literature, two of the latest contributions at this writing being those by Damien and Robinson,¹ in which further references to literature will be found.

In the following article the writer has therefore considered higher harmonics under such general conditions for both star and mesh connection. It is shown which harmonics cannot exist in the mesh voltage although present in the star voltages and which harmonics give rise to circulating currents in a mesh. The phenomenon of oscillating neutral is explained, and the effect of secondary mesh currents in furnishing transformer magnetizing currents is discussed. Polyphase magnetomotive forces are treated in the most general case when harmonics are present both in time and in space. Formulas are given for the order of harmonics which produce gliding and pulsating mmfs.

STAR AND MESH VOLTAGES

Let the armature windings of an m -phase alternator be star-connected, and let an n th harmonic be present in each induced electromotive force. This harmonic may be due, for example, to the distribution of the field flux in the air gap. The time-phase angle between the emfs. of fundamental frequency in the adjacent windings is $2\pi/m$, while the corresponding angle between the corresponding n th harmonics is $2\pi n/m$, because their frequency is n times greater.

Let the windings and the line terminals be numbered consecutively 1, 2, 3, . . . k , . . . $(m-1)$, m , and let it be required to find the value of E_n between the terminals 1 and $(k+1)$. The value of e_n is supposed to be known.

MEANING OF SYMBOLS USED

- e_n = star voltage due to the n th harmonic.
- E_n = mesh voltage due to the n th harmonic.
- E_r = resultant voltage around the mesh.
- k = consecutive number of a phase winding or terminal.
- m = number of phases.
- n = order of a harmonic in time.
- N = order of a harmonic in space.
- p = an integer.
- X = reference axis.

The vector E_n is a geometric difference between the vectors e_n of the star voltages in phases 1 and $(k+1)$. These vectors are displaced by an electrical angle $2\pi nk/m$ with respect to each other. From the isosceles triangle e_n, e_n, E_n one readily finds that $E_n = 2e_n \sin(\pi nk/m)$.

The following particular cases are of interest: (a) $kn/m = p$; $E_n = 0$. (b) $k = 1$; $n/m = p$; $E_n = 0$; this is a generalization of the familiar fact that in a balanced three-phase system no harmonics which are multiples of three exist in delta voltages. (c) $kn/m = p + 0.5$; $E_n = 2e_n = \max$; this is possible with m even. (d) Let it be required that $E_n/e_n = E_1/e_1$; that is, the star and mesh harmonics in the voltage are to be in the same proportion as their fundamentals. Then the condition to be fulfilled is that $\sin(\pi nk/m) = \pm \sin(\pi k/m)$, or $\pi nk/m \pm \pi k/m = \pi p$, from which $(n \pm 1)k/m = p$. Thus, in a three-phase system this condition is satisfied for the harmonics of the order $n = 2, 4, 5, 7$, etc.; that is, for those not multiple of three.

EXPLANATION OF OSCILLATING NEUTRAL

The time angle between the star voltages e_1 of the fundamental frequency in two adjacent windings is $2\pi/m$. For the n th harmonic voltage e_n this angle is $2\pi n/m$. When $n = m$ all of the e_n 's are in time phase with each other, so that with respect to this particular harmonic all the star windings are like parallel branches of a single-phase winding. Let the neutral point of the generator be grounded and let that of a star-connected load at the other end of the line be insulated. The potential of the insulated neutral point will then vary periodically above and below that of the ground at the frequency of the n th harmonic, these variations being caused by the voltages e_n . This phenomenon is known as the oscillating neutral. It also is caused by the harmonics of the order $2m, 3m$, etc. If now the second neutral point be also grounded, considerable harmonic currents of the above frequencies will flow through the system and through the ground connections. The troubles due to the oscillating neutral and to harmonic currents in the three-phase system are well known to operating engineers, and the remedies need not be discussed here.

CURRENTS IN STAR AND IN MESH

Let the windings of an m -phase armature be connected in mesh. The voltage vectors of the fundamental frequency are displaced by $2\pi/m$, and their addition gives a regular closed polygon. In other words, the resultant fundamental voltage around a mesh is equal to zero. This fact makes the use of such a connection possible.

For the n th harmonic the time angle between the voltages in consecutive phases is $2\pi n/m$, and the polygon which represents the addition of vectors may be

*Presented before the American Association for the Advancement of Science, Section D, Dec. 29, 1917.

¹Jacques Damien, *Revue Générale de l'Electricité*, Vol. II (1917), p. 363; Lloyd N. Robinson, *Proceedings A. I. E. E.*, Vol. 36 (1917), p. 967.

regular, multiple re-entrant or star-shaped. As an example, the reader may draw polygons for the fundamental, the third and the fifth harmonics in a symmetrical twelve-phase system, to see the difference in their shape.

It is of interest to determine whether or not the resultant n th harmonic voltage around a mesh is always equal to zero. Take the direction of the voltage vector in phase 1 as the reference axis X . The vector of the k th phase voltage forms with this axis an angle equal to $2\pi n(k-1)/m$. Therefore the projection of the resultant vector E upon the axis is

$$E_r \cos(E_r X) = E_n \sum_{k=1}^{k=n} \cos 2\pi n(k-1)/m.$$

The angles follow an arithmetical progression and the vectors are uniformly distributed over a total angle $2\pi n$. Hence the resultant E_r is equal to zero, except when all the vectors E_n are in phase with one another. This latter exceptional condition obtains when n is a multiple of m , so that each cosine is equal to unity. In this case ($n = pm$) or $E_r = mE_{pm}$. Thus, in an m -phase mesh-connected system the harmonic emfs. of the order m , $2m$, $3m$, etc., are not canceled but may give rise to a considerable internal circulating current. It is a well-known fact that in a three-phase delta-connected winding circulating currents are sometimes observed, which are caused by the third, ninth, fifteenth, etc., harmonics of the voltage.

MAGNETIZING CURRENT IN SATURATED TRANSFORMER CORES

When a single-phase transformer core is saturated and the applied voltage is sinusoidal, the magnetizing current has a peaked wave form. The effect of hysteresis is to make the wave also unsymmetrical. Thus, generally speaking, in a transformer with a saturated core the magnetizing current has various harmonics, both odd and even, superimposed upon the fundamental current. In a bank of m star-connected transformers, with the neutral insulated, some of these harmonic currents cannot flow. Namely, the currents of frequency $n = m$, are in phase with one another in all the phases, and the same is true of the currents of frequencies $2m$, $3m$, etc. All such currents require two ground connections in order to form a closed circuit. But if these currents cannot exist, then generally speaking the induced counter-emf. of the transformers cannot be sinusoidal; it must have voltage harmonics of the order $n = m$, $2m$, $3m$, etc. This leads again to the phenomenon of oscillating neutral described before.

Let now the secondary windings of these transformers be mesh-connected. The harmonic voltages of frequency m , $2m$, $3m$, etc., are all in phase with one another, as has been shown above, and they cause circulating currents in the mesh connection. These currents tend to neutralize the corresponding harmonics in the flux and in the voltage and thus counteract the formation of an oscillating neutral. Another way of describing this phenomenon is to say that the secondary mesh furnishes the lacking primary harmonics in the magnetizing current. This is one reason for which transmission engineers often prefer the Y-delta connection of transformers.

Sometimes one m -phase transformer may be used in place of m -single-phase transformers; that is, a trans-

former with m -windings and m -interlinked iron cores, the same being provided with two common yokes for flux return. With a star connection of the windings, the m th, $2m$ th, $3m$ th, etc., harmonics are lacking in the magnetizing current, the same as in the case considered above. But, in addition, the fluxes of these frequencies are also limited on account of the common yokes. In other words, the polyphase magnetic circuit is also star-connected, and the harmonic fluxes of these frequencies, being all in time phase with one another, "buck" each other and have to find closed paths through the air.

MMFS. OF POLYPHASE ARMATURE WINDINGS WITH SINUSOIDAL MAGNETIZING CURRENTS

Consider a regular m -phase winding such as would be used in the armature of a synchronous machine or on the stator of an induction machine. The simplest element of such a winding is one turn consisting of two conductors 180 electrical degrees apart. At a certain constant value of the current such a turn produces a "rectangular" distribution of mmf. along the air gap. The mmf. has a certain constant value for 180 electrical degrees and then an equal and opposite value for the next 180 degrees. For convenience of analysis such a rectangular distribution in space is replaced by a series of sinusoidal distributions.² The frequencies in space of the higher harmonics of this distribution will be denoted by N to distinguish them from frequencies in time of the harmonics of the magnetizing current considered in the next section and denoted by n .

First, let us assume the magnetizing current to be truly sinusoidal in time, only the harmonics in space being present. As the magnetizing current varies in time, the space harmonics of the mmf. pulsate at the same rate. But an alternating mmf. can be replaced by two mmfs. gliding synchronously in space in the opposite directions. Thus, finally, each phase of the winding produces an infinite number of sinusoidal mmfs. of various wave lengths (space frequency), some gliding to the left, others to the right. The harmonics of each frequency belonging to all the phases are combined into one wave, and the following combinations are possible:

(a) The waves going to the left have a resultant equal to zero, while those going to the right are combined into a larger resultant wave.

(b) The same statement as (a) with the words "left" and "right" interchanged.

(c) Both left-going and right-going waves are canceled.

(d) Both the left-going and the right-going waves have a resultant different from zero, and the resultant waves are combined into a pulsating one. This case arises only when the magnetizing current has harmonics in time; see below.

Let us assume that the fundamental flux glides from right to left, so that the fundamental current in any phase winding lags by $2\pi/m$ with respect to the one in the adjacent winding to its right. Consider now the N th harmonic waves belonging to these two phases and gliding to the left. It is shown in "The Magnetic Circuit," page 138, that in a three-phase winding these waves follow each other at an angle $2\pi(N-1)/3$. By a similar reasoning one can prove that in an m -phase system these waves follow each other at an angle

²See, for example, the author's "Magnetic Circuit" (McGraw-Hill Company), pp. 123 to 138.

$2\pi(N-1)/m$. The waves gliding to the right follow each other at an angle $2\pi(N+1)/m$.

But m equal sinusoidal waves uniformly spaced over a total angle of 2π , or over any multiple of 2π , give a resultant equal to zero. The only exception is when the angular distance between two consecutive waves is 2π or a multiple thereof, because then all the waves are simply superimposed. In our case this means that either $(N-1)$ or $(N+1)$ must be a multiple of m . Thus, in an m -phase winding with purely sinusoidal magnetizing currents and with the main flux traveling to the left the following harmonics³ only can be present:

Gliding to the left:

$N = 1$ (fundamental)

$N = m + 1,$

$N = 2m + 1,$

$N = 3m + 1,$

$N = 4m + 1,$

etc.

Gliding to the right:

$N = m - 1,$

$N = 2m - 1,$

$N = 3m - 1,$

$N = 4m - 1,$

etc.

Both odd and even harmonics are included in this table for the sake of generality. The latter may be present in an exceptional case of unsymmetrical consecutive poles.

As an application of the above table we find that in a three-phase winding the flux harmonics which are multiples of three are absent, and that of the other odd harmonics the seventh, the thirteenth, the nineteenth, etc., travel with the main flux, while the fifth, the eleventh, the seventeenth, etc., glide against it.

EFFECT OF HIGHER HARMONICS IN THE MAGNETIZING CURRENT

If the magnetizing current possesses an n th harmonic (in time) the mmf. waves (in space) which such a harmonic produces pulsate n times faster than the corresponding mmf. harmonics due to the fundamental current. Therefore, the component gliding waves also move n times faster. By comparison with the foregoing formulas we find that for the N th harmonic in space due to the n th harmonic in time the angular distance between the adjacent waves moving to the left is $\pm 2\pi(N-n)/m$; the angular distance between the adjacent waves moving to the right is $\pm 2\pi(N+n)/m$.

Many sets of the waves give a resultant wave equal to zero, and only those have a real existence for which either $N = n$, $(N-n)$ is a multiple of m , or $(N+n)$ is a multiple of m .

The mmf. waves for which $N = n$ are of particular interest, because their direction and speed of rotation are the same as for the fundamental mmf., and they cause a permanent distortion of the revolving flux. For other harmonics the speed of rotation is (n/N) times that of the fundamental, and their effect is often wiped out by eddy currents induced in the rotor bars or in some other part of the machine.

Another interesting case is when N and n separately are multiples of m . In this case both $(N-n)$ and $(N+n)$ are multiples of m , and therefore the resultant left-going and right-going waves are equal to each other and are different from zero. The two resultant waves added give a stationary pulsating mmf. For example, in a three-phase induction motor the third harmonic of the magnetizing current ($n=3$) causes part of the third and ninth harmonics of the mmf. ($N=3$ or $N=9$) to be stationary in space.

For the sake of generality it has been assumed above that all the space harmonics are present. In reality some of them can be neutralized or considerably reduced by a judicious use of a fractional-pitch winding, but this topic is outside the present discussion.⁴

Recapitulating:

(a) The waves that glide in the same direction as the fundamental are those for which either $N = n$ or $\pm(N-n) = pm$.

(b) The waves that glide against the fundamental are those for which $N + n = pm$.

(c) Pulsating waves are caused by harmonics for which $N = pm$ and $n = pm$.

(d) No waves can exist for which neither $(N+n)$ nor $(N-n)$ is a multiple of m ; the case of $N-n=0$ is covered in (a) above.

The foregoing rules can be readily used to check the table given without proof in Arnold (*ibid.*), page 275, for two-phase and three-phase machines.

ELECTRIC ARMY KITCHEN FOR FIELD-SERVICE USE

Portable Device Adapted to Motor Trucks Using Exhaust to Supplement the Heat Derived by Means of Electricity

One of the developments made in the utilization of electricity for war purposes is a portable electric army kitchen designed to be used on the Smith "form-a-truck." This kitchen has been carefully worked out to meet requirements of Red Cross and army field service. The kitchen heat is obtained by the combination use of

PORTABLE ELECTRIC KITCHEN FOR ARMY USE

an electric generator driven by the automobile motor and the heat from the exhaust of the motor, which amplifies the heat obtained through use of electricity.

The portable army kitchen is equipped with two 30-gal. (113-l.) fireless cookers, with a twenty-six-hour cooking head efficiency; a 30-gal. coffee urn, a 30-gal. vegetable and soup urn, baking and warming ovens, and two large hot-water sterilizing tanks, which are designed to sterilize 120 gal. (454 l.) of water in two hours. The generator develops a current which is said to throw a searchlight ray for 3 miles (4.8 km.) and will carry the load of 600 110-volt lamps.

Because of the tie-up of the generator with the automobile motor this kitchen can be operated either while traveling or while at rest.

³See also deduction by E. Arnold, *Wechselstromtechnik*, Vol. III (1912), p. 243.

Operating Temperatures in Large A.-C. Generators

Obstacles to Calculating Maximum Operating Temperatures from External Temperatures —Comparisons of Resistance, Thermometer, Exploring Coil and Thermocouple Methods of Measuring Temperatures

BY H. D. STEPHENS

Manager of Generator Section, Westinghouse Electric & Manufacturing Company

THE large amount of capital invested in generating equipment, the expense of repairs and the loss of revenue resulting from its shut-down all make it especially important that safe operation and continuity of service be assured. While the breakdown of insulation is not always the cause of apparatus failure, it is the cause often enough to make it essential to look into all conditions contributing to such breakdown and to ascertain how the approach of these conditions can be prevented or definitely determined.

One of the chief causes of insulator failure is excessive temperature, as all well-known insulators deteriorate rapidly when certain definite temperature limits are exceeded. These limits have been ascertained for most commercial insulations, but heretofore it has been a problem of determining when the prescribed temperature limit is exceeded. When thermometers have been used for this purpose the insulation apparently failed in some cases before the temperature limit determined by laboratory test was exceeded. This apparent disagreement was really due, however, to the fact that the thermometers were not placed where the maximum operating temperatures occurred. Later, when resistance-change measurements* were taken as indications of the temperature obtained, the point at which insulation breakdown occurred agreed more closely with that determined by test, but still there was a wide enough divergence to warrant looking into the cause of the difference. Obviously it was due to the fact that "hot spots" occurred and that the resistance measurements indicated only the average temperature of the entire circuit measured.

Since embedded temperature detectors have come into use, however, it has been possible to determine the maximum operating temperatures much more effectively as the thermocouple or exploring coil, the two types of detectors most generally used, can be installed where the hot spots are expected to occur. In fact, they have been found so effective that their use is becoming standardized in all large-size alternators having a core width of 20 in. (50.8 cm.) and in all machines wound for 5000 volts or over.

The exploring-coil type of detector consists of a coil of wire having a high resistance. Any change in resistance will be directly proportional to the temperature change; hence, if the resistance and corresponding temperature is known, the latter temperature can be readily calculated. The exploring-coil type of detector developed by the company with which the writer is connected consists of fine copper wire, is approximately 5 in. (12.7 cm.) long and has about 30 ohms resistance. The resistance is measured by a simple Wheatstone bridge (Fig. 3) arrangement in which the detector forms one of the four resistance arms.

*Coil with high-temperature coefficient embedded in part of apparatus of which the temperature is desired.

With this type of detector the readings will be absolutely accurate only when the temperature of the coil and leads is the same as that at which calibration took place. However, if the resistance of the coil is very high and the resistance of the leads relatively low, the percentage of error is very small indeed over the range of temperature found in practice. The fragility of the small exploring coil is its greatest drawback. If heavier wire were used for the coil, it would occupy more space in the slot, or the resistance would have to be made very much less. Further, even if only 5 in. (12.7 cm.) in length, it measures an average temperature over this entire distance in the core. If the core is only 20 in. (50.8 cm.) in width, the difference between the average

FIG. 1—TEMPERATURE VARIATION ALONG ARMATURE SLOT

and hot-spot temperature may be considerable, as the coil occupies 25 per cent of the width. A larger or longer coil will increase this percentage and render still greater the difference between the reading obtained and the actual "hot-spot" temperature.

The preceding disadvantages are absent with the thermocouple detector because the thermocouple registers the temperature at a single junction point, and it can be made of thin strong metal strips instead of very fine wire. The "hot" couple or junction point in the machine is at the point where the temperature is measured and connected to a "cold" couple in the temperature indicator. In the apparatus developed by one manufacturer this is a potentiometer of the galvanometer type arranged for switchboard mounting and with the measuring scale calibrated to read directly in degrees Centigrade.

The temperature as indicated by either the exploring coil or the thermocouple is practically valueless as an indication of safe operating conditions unless the detectors are installed at the spots where the highest temperatures will occur. These spots are difficult to determine because the resultant temperature is due to

several sources of heat, which may be widely different in different machines even if of the same general type, especially when there is a change of load or terminal voltage. For instance, heat results from the iron loss of the armature, from the resistance of the conductors, from eddy currents in the conductors proper, and from radiation from the field. Not only do these losses vary with change of load, but they may also be distributed unequally throughout the volume of the metal employed.

Further, as regards the dissipation of the heat generated in the conductors, it may flow along the conductor to the end turns, and thence through the insulation to the air, the thickness of the wall of insulation and its tightness making considerable difference in the heat drop resulting. On the other hand, the heat may flow through the insulation inside the core into the punchings. Here also two paths, widely differing in their conductivity, are available, one along the individual punchings to the back of the core, and the other through the punchings, with their separating walls of "japan," to the air passages spaced throughout the core.

In general, test data covering a large number of generators of different characteristics show the location of points of maximum temperature to be at or near the

ment of the "hottest-spot" temperatures is concerned. This has been due to a lack of definite data on the subject.

One scheme of connecting the equipment required with the thermocouple temperature detector is shown in Fig. 2. Six couples are ordinarily used per machine by the company with which the writer is connected, and the couples are made of thin ribbons of copper and Advance alloy welded together. The individual copper leads are run from the terminal board of the machine to the switchboard. A common Advance alloy lead forms the other side of the circuit. This keeps the wiring to a minimum and at the same time allows of reading on any one of the six couples employed. Where exploring coils are used, the same diagram as shown in Fig. 2 will apply except for the substitution of resistance coils for the couples and a standard type of voltmeter with scale marked and calibrated to read degrees centigrade.

Both methods of measurement described are superior to the older thermometer method for machines having large ratings. The detector is useful at times of heavy load in furnishing the operator with data so that the safe temperature of the insulation may not be exceeded

FIGS. 2, 3 AND 4—ONE METHOD OF CONNECTING THERMOCOUPLES WITH POTENTIOMETER; CONNECTIONS IN BRIDGE RESISTANCE BOX; BEST LOCATION FOR THERMOCUPLE TO DETECT MAXIMUM INTERNAL TEMPERATURE

center of the core and in the copper of the windings at this point. This is illustrated in Fig. 1, which shows a temperature curve obtained by installing a number of detectors at various points across the machine and all in the same armature slot.

The correct location for a detector in the armature slot is shown in Fig. 4. Nearly all modern alternators have two-coil-per-slot windings. Therefore, if the copper has the highest temperature, any location except that between the two conductors gives a reading intermediate between the temperature of copper and that of the iron, since the heat transfer from the hot to the cooler surface is accomplished only when a drop in temperature exists. When the two conductors in the same slot are at or near the same temperature, as they normally are, there is no tendency for heat transfer from one to the other, hence the detector at this point approximates the maximum temperature. Undoubtedly there are many large machines in service, equipped with temperature-indicating devices, whose temperature readings are absolutely valueless in so far as measure-

and to check conditions of operation to predetermined loads.

Accumulations of dust and dirt in the air passages of the machine will, for a given load, cause the operating temperature to rise. The detectors will give indications as to when such conditions exist and warn the operator to remedy them by cleaning the machine thoroughly. The use of detectors is not recommended for small-capacity machines because such units are usually narrow of core and have internal temperatures that differ but little from external accessible points. Furthermore, the armature slots are of such small proportions in these machines as to render the location of detectors either very difficult or impossible. Detectors cannot be used for measurement of temperatures of revolving fields of alternating-current generators nor for revolving armatures of direct-current generators because of the variable nature of the moving contacts and the large percentage of error that it would cause with such small values of current or voltage as are used in detector circuits.

Changing Aspects of Factory Lighting Legislation

Outline of the Proposed New Ohio Code and of the Principal Changes Which Have Been Made or Proposed in the Codes of the States of Wisconsin, Pennsylvania and New Jersey—Comparison with I. E. S. Code

BY C. E. CLEWELL

Assistant Professor of Electrical Engineering, University of Pennsylvania

The first part of this article reviewed the revisions and changes in the Factory Lighting Code of the Illuminating Engineering Society since June 1, 1917, emphasis being placed on the five chief elements on which these rules are based. This part outlines the new proposed code of Ohio and the principal changes which have been made or proposed in the codes of Wisconsin, Pennsylvania and New Jersey. While the intensity of illumination is only one of five important elements of the legislative rules, it is interesting to compare the values for various classes of work in the different codes and as given by several authorities. The table in this article is the most elaborate and recent compilation of factory lighting intensities by the author, and it indicates in readily comparable form the changes which have been made in state rules in 1917 and 1918.

IN THE first installment of this article, which appeared last week, it was pointed out that the principal items included in the latest revision (1917) of the Illuminating Engineering Society's Factory Lighting Code are: (a) Illumination intensity requirements for various classes of work, (b) elimination of glare, (c) distribution of light on the work, (d) emergency lighting, and (e) pilot or night lamp control near entrances. The purpose of the present article is to discuss some of these items on a basis of more complete or modified specifications than those outlined by the factory code of the Illuminating Engineering Society, which were given in Part I of this article. Certain changes in the manner of specification have been suggested by some of the state authorities who are revising old or preparing new codes of this kind.

INTENSITY REQUIREMENTS

For reasons which have been fully discussed in previous articles¹ the original I. E. S. Code made a radical departure by specifying the quantities of light for various classes of work in terms of the illumination intensity in foot-candles at the work. Two problems were faced in making such a specification, namely, (a) the proper classification of work and (b) the difficulty in checking up intensities when inspecting lighting conditions. Item (b) has been rendered much more possible by the appearance of the foot-candle meter as a simple and inexpensive instrument for the purpose.

Item (a) has led to some discussion on the wisdom of possibly having a more complete classification of work than that contained in the present I. E. S. Code. Wisconsin, Pennsylvania and New Jersey have practically decided to adopt a classification similar to that of the I. E. S. Code. In Ohio the effort has been made to use a much more extended classification in conjunction with the brief list as given by the I. E. S. Code and as given essentially in the accompanying table.

The proposed Ohio code contains, for example, six main headings for its work classifications and then adds an appendix containing about 250 classes of work, each

of which is classified under one of the six heads in the main list. While this kind of elaborate classification is commendable as an effort to aid the factory inspector quickly to place any given shop section in its proper class, it is open to two objections.

On the one hand, such a detailed classification accentuates the intensity specification and tends to minimize the importance of other regulations in the code, and, on the other hand, the elaborate list of detailed classes of work tends to make the code rigid and to eliminate the judgment of the inspector. Experts in the factory lighting field tend to view the present situation as one which demands even greater attention to glare than to intensity. This is evidenced by a statement like the following from an important report on industrial lighting:

"While it is desirable to have adequate light over the working areas, it is absolutely essential for the proper results to eliminate or minimize the light which otherwise would pass directly from the lamps to the eyes of the workers; that is, one must avoid glare, which is not only fatiguing to the eye but also conducive to the incorrect estimation of sizes and locations of objects in the field of view."

There seems to be a danger, therefore, that any code which is overburdened with too extended a classification of working processes will lead the average factory inspector to concentrate his attention on these elaborate lists in an effort to find how to classify a given kind of work, and that this very effort will have a tendency to make him overlook other and possibly more important code regulations. In other words, the current opinion is that a classification somewhat like that in the accompanying table is more flexible and, by leaving to the inspector the selection of any one of six or eight general heads to apply to a given factory section, renders him more free and consequently more likely to emphasize the other rules of the code with which he happens to be concerned.

THE TABLE OF INTENSITIES

The accompanying table of intensity of illumination in foot-candles required by various codes and by rules from other sources is probably the most complete compilation of such figures which has been possible up to date because of the very recent additions which code revisions and new codes have made to previous tables of this character.

The values given in this table furnish a convenient basis for comparing the intensity recommendations in old and revised codes and also those of older codes with the proposed newer regulations. It is desirable, however, not to lay too much stress on differences which may occur for any given class of work in the various columns since it is practically impossible in compiling such figures to be sure that the class of work con-

¹ELECTRICAL WORLD, Vol. 66, No. 21, page 1135, and Vol. 69, No. 25, page 1203.

sidered was exactly the same in each case. Thus, rough manufacturing might have meant one thing in one case and something different in another.

However, each column of the table indicates whether the intensity is a minimum or ordinary practice. In column (2) the values listed for ordinary practice

desire to reduce all proposed rules to as definite a basis as is possible with the existing state of the art. Up to the present time, however, it has not felt able to make a more definite rule regarding the shading of lamps than that given in Rule 3.

Interesting suggestions have been made, however, for

*The intensity values given in column 3 of the table were estimated by the author from specifications of candle-power per square foot as listed in the original Wisconsin orders of 1913. Columns 4 and 5 give the actual foot-candle intensities as listed in the 1917 Wisconsin Handbook.

†In the 1915 British report there are no specifications of illumination intensities required for the work, and hence the values as given in column 10 of the table refer merely to general illumination recommendations as listed in the British report and have no regard to the needs of the work itself.

are, in general, means between two values given as limits in the handbook of the General Electric Company. Of the four states which have drafted codes thus far with the I. E. S. Code as a basis, each has followed the general plan of reducing the classification of work to a few headings, with the possible exception of Ohio, which has added the more comprehensive list as a supplement to the code proper.

There has been some call for a more definite specification of glare as an aid to the interpretation of the

drafting a definite rule on glare, notably by the Industrial Commission of Wisconsin, where an unusual amount of time and much commendable effort have been consumed to revise the older shop-lighting "orders" of 1913. The first effort of that commission to draft such a definite ruling on glare took the following form:

"Lamps within the glare angle shall be shaded in such a manner that the brightness of any part of the light source or accessory does not exceed 50 candles per square inch (7.75 candles per sq. cm.). When the

FIG. 1—AN EXAMPLE OF THE IMPORTANCE OF APPROXIMATELY UNIFORM ILLUMINATION ON HORIZONTAL SURFACES

FIG. 2—UNIFORM ILLUMINATION ON HORIZONTAL SURFACES MAY RESULT IN POOR VERTICAL-SURFACE ILLUMINATION

rule and for the help of inspectors who are called upon to determine when the limits of glare are exceeded. Recognizing this need in a broader way, the committee on lighting legislation of the I. E. S. has evidenced a

line between the eye of a person stationed at one end of a room and the most distant light source makes an angle of 45 deg. or more with the vertical, the lamp

"Lamps shall be suitably shaded to minimize glare."

will be considered within the glare angle in interpreting this order."

A diagram illustrating how such a proposed ruling might apply to a given case is shown in Fig. 3. Apparently, from this diagram, practically all lamps would always fall below this glare-limiting angle in shop sections with the common ceiling height of approximately 20 ft. (6.1 m.).

This proposed glare rule has naturally resulted in much discussion, some experts contending that an angle

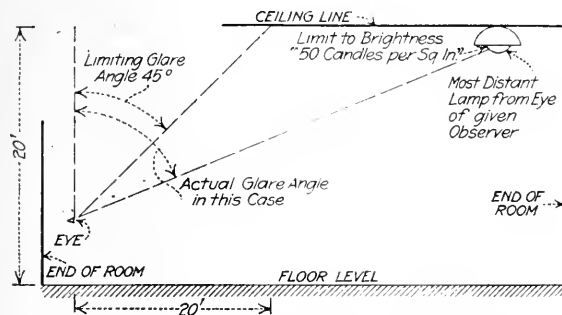

FIG. 3—DIAGRAM OF CONDITIONS CORRESPONDING TO ONE SUGGESTION WHICH HAS BEEN MADE FOR RENDERING A GLARE SPECIFICATION MORE DEFINITE

of 45 deg., as in Fig. 3, is too drastic, some that a brightness of 50 candles per square inch (7.75 candles per sq. cm.) is too low for certain cases, and others that it is much too high, the latter contention being based in one case on the fact that the I. E. S. committee on glare had previously gone on record as favoring a lower limit of brightness for lamps within the glare angle.

Toward the latter part of 1917 the Wisconsin suggestion was somewhat modified to the following effect:

Shading of Lamps.—Lamps for overhead lighting, suspended at elevations above eye level, less than one-fourth their distances from any position at which work is performed, shall be shaded in such a manner that the maximum brightness of the light source shall not exceed 75 candles per square inch (11.6 candles per sq. cm.).

Exception.—Lamps suspended at greater elevations than 20 ft. (6.1 m.) above the floor are not subject to this requirement.

Lamps for localized lighting, suspended at or near the eye level, shall be shaded in such a manner that the brightness of the surface presented to view from any position at which work is performed shall not exceed 2 candles per square inch (0.31 candle per sq. cm.)

It should be remembered that both of these proposed rules on glare have thus far been purely suggestive, and that the committee on lighting legislation of the Illuminating Engineering Society, although in sympathy with such efforts, has not yet gone on record with any more definite wording for glare than that given as Rule 3 above.

It is very interesting to note, however, that another modification of the Wisconsin proposed glare rule has been suggested, and this is added because of its important bearing on this topic.

MODIFICATIONS OF PROPOSED WISCONSIN GLARE RULE

Shading of Lamps.—Lamps shall be suitably shaded to minimize glare.

Note 1. In many interiors where overhead lighting is used a brightness for artificial light sources not exceeding that of the sky (two to three candles per square inch) will prove desirable. The rule prohibits absolutely the use of lamps for overhead lighting suspended at elevations above the eye level less than one-fourth their distance from any

position at which work is performed, unless they are shaded in such a manner that the intensity of the brightness of the visible light source does not exceed 75 candles per square inch (11.6 candles per sq. cm.).

Exception.—Lamps suspended at greater elevations than 20 ft. (6.1 m.) above the floor are not subject to the requirement stated in this note.

Note 2. In the case of lamps used for localized lighting suspended at or near the eye level the limits of permissible brightness are much lower than those given in Note 1. The rule does not permit the use of local lamps unless shaded in such a manner that the brightest surface exposed to view from any position at which work is performed does not exceed 2 candles per square inch (0.31 candle per sq. cm.).

Note 3. Where the principal work is performed on polished surfaces, such as polished metal, celluloid, etc., it is advisable (although at present not mandatory) that the limit of 75 candles per square inch be made to apply to the intensity of the source in all downward directions in order that the reflected glare from such surfaces may also be minimized.

Note 4. Glare either from lamps or from unduly bright reflecting surfaces produces eye strain and increases accident hazard.

The foregoing wording and the arrangement of notes following the rule proper possess a number of advantages over either of the two preceding proposed glare rules, chief of which is the emphasis placed on the desirability of keeping down to much lower limits than the value of 75 candles per square inch as given in Note 1. The conditions which would correspond with Note 1 of the last proposed glare rule are shown by Fig. 4. This diagram will give the reader a basis for picturing just what proportions the rule plans to cover.

DISTRIBUTION OF LIGHT ON THE WORK

Rule 4 of the revised I. E. S. Code reads as follows:

Distribution of Light on Work.—Lamps shall be so installed in regard to height, spacing, reflectors or other accessories as to secure a good distribution of light on the work, avoiding objectionable shadows and sharp contrasts of intensity.

To avoid the indefiniteness of the expression "a good distribution of light on the work" the Industrial Commission of Wisconsin, in the fall of 1917, suggested the following modification of the I. E. S. rule:

The reflectors or other accessories, mounting height and spacing employed with lamps shall be such as to secure a

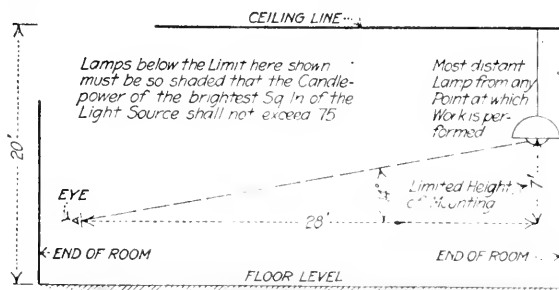

FIG. 4—DIAGRAM OF CONDITIONS CORRESPONDING TO ANOTHER SUGGESTION WHICH HAS BEEN MADE FOR RENDERING THE SPECIFICATION OF GLARE MORE DEFINITE

uniform distribution of illumination on the work, avoiding objectionable shadows and sharp contrasts of brightness.

Note. This order forbids the use of local lamps only, since with their use the field of illumination from each lamp is in sharp contrast to the surrounding darkness and causes severe eye strain and increases the accident hazard.

When local lighting is used there must be employed in addition a moderate intensity of overhead lighting uniformly distributed.

By uniform lighting is meant illumination such that the

ratio of maximum to minimum intensity at the work, for similar operations, will not exceed three, and between the work and adjoining aisles or passages, twenty.

This suggestion for a more definite rule on light distribution has also caused much discussion, and as one result a revised suggestion has been made which has some advantages over the suggested ruling as just given. The main clause of this revised rule, as proposed, is exactly the same as the first paragraph of the above rule except that the word "reasonably" is inserted just before the word uniform, and a note is appended as follows:

Note. This order forbids the use of local lamps as the sole source of illumination even if properly shaded, since with their use the field of illumination from each lamp is in sharp contrast to the surrounding darkness, thereby causing eye-strain and increasing the accident hazard.

When local lighting is used there must be employed in addition a moderate intensity of overhead lighting reasonably uniformly distributed.

It will be noted that this second proposed "distribution" rule omits any reference to an exact ratio of maximum to minimum. It has been felt that even this proposed rule, which is considerably less drastic, might work a hardship for some cases where a system of local lamps is in service with white ceiling and white or very light surfaces beneath, since sufficient general illumination may result indirectly from the local lamps to make additional overhead lighting unnecessary. Figs. 1 and 2 suggest cases where a definite specification of uniform illumination on horizontal surfaces might or might not prove adequate for the needs of the case.

MODIFICATIONS IN STATE RULES

The foregoing comments on "glare" and "distribution" cover the principal points which were involved in the preparation of the revised Wisconsin rules. They constitute points of fundamental importance, but, as already stated, the I. E. S. committee on lighting legislation has not seen fit thus far to modify its rules on these items any further than as outlined in the previous article. In case Wisconsin should decide in the end to incorporate one or another of the foregoing proposed definite rules, an opportunity would thus be afforded to try them out under actual working conditions. The additional information thus gathered would doubtless prove of value in reducing some of the I. E. S. Code rules to more definite form later on.

The Ohio code, as proposed, follows the general plan of the I. E. S. Code, but omits any reference to emergency lighting and controlling apparatus and appends the extended detail classification, under some two to three hundred heads, of various kinds of work in many industries.

The 1918 proposed revisions of the Pennsylvania and New Jersey codes include in practical entirety the revised I. E. S. Code of June, 1917, with a very slight change in Rule 3 and in Rule 6.

Two fundamental points must be covered before state factory lighting legislation can be enforced effectively. One is the availability of an inexpensive and fairly simple portable photometer. The new foot-candle meter meets this condition as far as the development of the instrument is concerned. However, the state departments of labor will be obliged to place a number of these instruments in the hands of their inspectors before much progress can be made.

The other point is that the inspectors in nearly all cases will require some instruction in the elements and practice of factory lighting before they can go through a factory and determine whether or not the rules of a code are being complied with. Engineers of various labor departments lay great stress on this latter point.

It is thus of peculiar importance at this time to record the arrangement which has just been completed between the Commissioner of Labor of Pennsylvania and the provost of the University of Pennsylvania whereby a course of lectures on factory lighting is to be given to the factory inspectors both of Pennsylvania and of New Jersey. This is a starting point along the lines of instruction for state inspection departments the importance of which can hardly be overestimated.

THE WAY TO JOIN THE ENGINEERS OF THE ARMY

First Replacement Regiment of Engineers Organized to Keep Army Engineering Units at Full Enlistment Strength

The German Kaiser has placed the keenest engineering talent of his own and allied empires into the imperial armies of the Central Powers to defeat the world. During these last three years the best engineering skill of France, Great Britain, Russia and Italy and their allies has been matched against the enemy. American employers are paying engineers such attractive salaries that voluntary enlistments of the high-class technical men in the United States Army are below requirements. This deficiency is also probably due in part to the lack of proper information concerning the engineering branch of the service. Few civilians know that it is possible for them to perform in the Engineering Corps almost exactly the same kind of work which they are now doing. The First Replacement Regiment of Engineers was organized at Washington Barracks, D. C., on Dec. 14, 1917, with the express idea of accomplishing this end. Its specific purpose is to keep all engineering units of the army at full enlistment strength during the period of this war. This regiment has not only the responsibility of finding men to fill up depleted ranks, but it must also fit them to become trained, efficient and disciplined soldiers.

The Replacement Regiment will be called upon to furnish men for the following organizations: Camouflage regiments, crane operating and maintenance regiments, depot detachments, electrical and mechanical regiments, forestry (sawmill) battalions, forestry (auxiliary road, camp and bridge) battalions, gas and flame service, general construction battalions, mining regiments, quarry regiments, sapper regiments, searchlight regiments, supply and shop battalions, surveying, ranging and map reproduction regiments, and water-supply companies.

To be assured of assignment to this regiment, the applicant for enlistment should write to the commanding officer of the First Replacement Regiment Engineers, Room 107, Headquarters Building, Post of Washington Barracks, D. C., for application blank. If the blank shows the man to be eligible, an enlistment card is filled out and sent to the recruiting officer nearest to the applicant's place of residence, with instructions to enlist the man for service in this regiment.

Liberty Loan and Labor

Details of the Way in Which the Coming Third Issue of Bonds Can Be
Employed to Stabilize Employment Conditions—New
York Plan for Floating Loan

THIS week's daily papers have contained the financial details of the third Liberty loan as announced by the Secretary of the Treasury. With the details known, the week remaining before the national campaign opens gives sufficient time to every company to decide definitely on the size of the company subscription and on the way in which the company will handle employee subscriptions, and also to perfect all plans for assuring 100 per cent subscription in the plant, office and factory.

So far as can be learned, very little has been done yet in preparation for the third loan. Employers must get ready. There is but one more week left before the campaign opens. The campaign will last only three weeks. It will take the whole of the three weeks to insure the desired 100 per cent subscriptions.

NEW YORK CITY PLAN

In New York City the electrical industry is making progress with its preliminary work. There are two general committees—one of the utility interests and the other of the remaining electrical interests. The second committee has seven divisional committees as follows: (1) Manufacturers; (2) jobbers; (3) contractors and dealers; (4) manufacturers' agents; (5) manufacturers' branch offices; (6) electrical inspectors, and (7) labor. In addition, there are two auxiliary committees, one of central stations and the other of electrical societies.

The general committee has a chairman, a vice-chairman, a secretary, an assistant secretary and a publicity director. This committee will help the divisions, which must work out their own individual plans. The committee has a professional bond salesman who is showing the members how to sell and how not to sell Liberty bonds.

Louis Kalischer has been appointed chairman for the contractor-dealer group, George Patterson for the electrical jobbers' division, J. Nelson Shreve for electrical manufacturers of New York City, Charles Crofoot for manufacturers' agents, E. D. Kilburn for New York branches of manufacturers, J. M. Wakeman for electrical societies, J. C. Forsythe for New York Underwriters, A. Goldman for central-station auxiliaries, and William Walsh for inside electrical workers.

Arrangements are being made to have all subscriptions by members of the electrical industry in New York City made through the electrical committee. The committee is also making arrangements to have a speaker at every meeting of an electrical society during the three weeks of the campaign.

In the past loan campaigns a great number of striking plans were worked out, but the purpose of these articles is not to show extraordinary methods but, rather, simple, workable plans that bring maximum returns.

In manufacturing plants, especially where there is any considerable foreign element among those em-

ployed, the following method has been known to get results. Each foreman is supplied by the employer with a number of blank forms—one for every employee under his direction. The foremen give the blanks to their men, who in turn must either signify their intention of subscribing to the loan or else state in writing on the blank their reason for not so doing.

There will, of course, be a number of men who for some reason or another cannot subscribe to the loan at the moment. These men may be able to subscribe later, and the method that naturally suggests itself in the third loan, provided that the individual has participated in the first or second loan, or both, is to accept his previous bonds as collateral in order to finance the purchase of the third issue.

Furthermore, it will probably be found that this latter method will help a number of holders of first and second loans to subscribe to the third. There will undoubtedly be a disposition on the part of those in the first and second loans to feel that they have about all they can carry for the present at least.

Another method for getting employee subscriptions that has been found to work well from every angle is very apropos under prevailing labor conditions. Under this plan the employer pays a certain proportion of the bond, provided that the employee remains in his employ until the whole sum is paid. Nor is it possible to pay other than at a certain rate.

Thus, one employer has been selling his men one-hundred-dollar bonds for \$75 in weekly payments of \$1.50. If an employee leaves the service of the company prior to the end of the fifty weeks, he loses the twenty-five dollar bonus, for that is what it really amounts to. The longer the employee remains the nearer the \$25 is and the more difficult it is to leave.

This particular employer takes the position that in these times it is worth \$25 to keep a good workman for a year. In a shop of, say, 100 men, provided that all subscribed, the cost would be but \$2,500 to keep the force practically intact for a year. It is doubtful if this could be done so cheaply in any other way.

PAYMENT COLLECTION

It is not necessary for a company to collect the installments on the bonds. In fact, it might be best to have some bank in the neighborhood handle this matter, for the reason that the habit of going to the bank weekly to make a deposit will in this way be encouraged. American labor needs some such stimulus to save, and by saving labor will become steadier.

Regularity in making payments, however, must be insisted on. Some companies take the required amount out of the pay each week. Others send a clerk around to each bondholder on pay days. If it is all left to the employee, there are a number who will allow the matter to slip until they find themselves in deep water. In such instances the purpose of the loan will largely be defeated.

Prevalent Trend of Domestic Appliance Market

Demand by the Public for Less Expensive Type of Goods Is Seen—How the Portable Lamp Trade Will Meet This Demand—Utility Rather than Luxury Is the Desideratum with the Rapidly Growing Clientele

BY E. A. EDKINS

General Manager of Electric Shops, Commonwealth Edison Company

IT APPEARS to me that there is a growing demand on the part of the buying public for less expensive electrical merchandise. The records of sales in the five electric shops of the Commonwealth Edison Company bear out this belief. Moreover, personal observations of prospective customers who are making selections of domestic appliances also assist in verifying these conclusions. By this I do not mean that I believe manufacturers' prices on existing types of merchandise are too high. Under the existing market conditions the prices could hardly be expected to assume other than their present level. What I do mean is that the class of people who are the potential buyers of electrical goods is not the same as the class that was in the market one year or two years ago. The world war has changed that, and the potential buyers of today are looking for types of merchandise that are less expensive than those which the electrical trade is showing. I do not believe in cutting prices to meet this demand, but I do believe in producing types of merchandise to satisfy it.

It may be well to analyze the situations which have brought about this condition. The reason the demand for less expensive goods has suddenly appeared will be found in the industrial conditions. The reason why the demand for expensive wares has decreased may be found in the declining stock market.

Conditions in the industrial world are such to-day that the workingman whose wages were formerly \$2 to \$3.50 a day now finds himself earning from \$6 to \$10 a day. Moreover, if he is a dependable workman, his services are in steady demand, whereas his employment was formerly more or less intermittent. The result is that he can, and in many cases does, save some money. Also he spends some, because he and his wife have for a long time looked forward to the day when fortune would make it possible for them to own certain home conveniences and comforts. Among the things they consider purchasing are electrical goods. But they do not consider the purchase of an alabaster lamp at \$250, nor do they spend much time investigating the convenience and utility of a ten-dollar waffle iron. They are looking for a portable lamp that does not cost much, will give good light and will make their home look cozy. Or perhaps they may want a medium-priced electric iron. That is the condition in the industrial working classes.

The wealthy people, who formerly walked into the shops, saw a beautiful lamp and bought it without asking the price are in a different frame of mind now. War taxes, Liberty bond purchases, the depreciated market value of securities they own, are to them all very real evidence of the necessity for cutting down purchases. These people are simply out of the market, and the sale of expensive merchandise is suffering accordingly. This is reflected in the sales of portable

lamps in the electric shops. A few years ago the average retail price per portable lamp sold was about \$25. To-day the average price is around \$15 or less.

Recognizing that these conditions exist, some steps have already been taken to get the waiting business. It was realized that the market exists for an attractive library table lamp at a lower price. As the result of several conferences with lamp manufacturers it developed that to produce the desired lamp at the desired price it would be necessary to have quantity production. There was no single lamp distributor who could place an order large enough to get that quantity price. Negotiations were then opened to see whether several central-station companies operating electric shops could agree to place an order which in the aggregate would be large enough to assure a manufacturer the econ-

THE PYRAMID OF MERCHANDISING POSSIBILITY

The volume of sales of any commodity may be represented by a pyramid. High-priced articles or style goods appealing to the luxury class of buyers have relatively small sales possibilities in volume, represented by area A. The great middle-class demand is represented relatively by area B. The utility and low-price market is the still larger area at the base of the pyramid. The electrical appliance field has been cultivated in general only in the luxury and the upper stratum of the middle-class market.

omies of quantity production. When the plan was proposed it met with instant favor. A lamp is now being created which will be marketed in the fall by this group of central stations at a price around \$7, which compares favorably in size, artistic design and intrinsic value with similar lamps now on the market that retail from \$15 to \$20. This incident indicates how strong and how general is the belief that the market for less expensive merchandise exists.

Another and somewhat different incident also has a bearing on this point. We were displaying some excellent electric waffle irons at \$10 each, the list price.

I persuaded some of my friends who I thought might be interested in them to go into the shop and examine them. The clerk, of course, explained the wonderful convenience and satisfaction of being able to sit at the breakfast table on Sunday morning and produce right there delicious crisp brown waffles. Everything went well until price was mentioned. I learned later that these same people left our shop, went down to a department store in the next block and bought a waffle iron of the type that operates from the gas stove and sells for 95 cents. When I talked to them about it later they said they would surely like to enjoy the convenience of the electric waffle iron, but that \$10 was too much money for an electric appliance when the gas-stove type cost only 95 cents. I explained that with the elec-

tric waffle iron the purchaser also got a stove. But the argument was unavailing, because they said they had the gas stove and might as well use it. An electric waffle iron that could be priced around \$5 would, I believe, have a big sale. Five dollars is a popular price.

The fact of the matter is that the group in the industry which is merchandising domestic electrical goods has hardly scratched the surface. We have all been appealing to the wealthy buyer. He is at the apex of the pyramid of sales possibilities. As we go toward the base of that pyramid the sales opportunities multiply at an astonishing pace. Educating the public, broadening the market and getting out less expensive merchandise all go hand in hand in the program of getting toward the pyramid's base.

Transmission Line Service in Illinois

Interconnected Electric Generating Systems Within the State and Also Connections with Other Companies Outside of the State—Districts Covered by the Lines of Twenty-eight Companies

Possibilities of interconnection in Illinois are of general interest to the central-station companies and of recognized importance to the nation as a measure for conserving fuel and power. Developments in the interconnection of electric generating systems have been followed closely in the ELECTRICAL WORLD. The issues of Jan. 5 and March 2, 1918, showed what is being done in New York, California and Massachusetts.

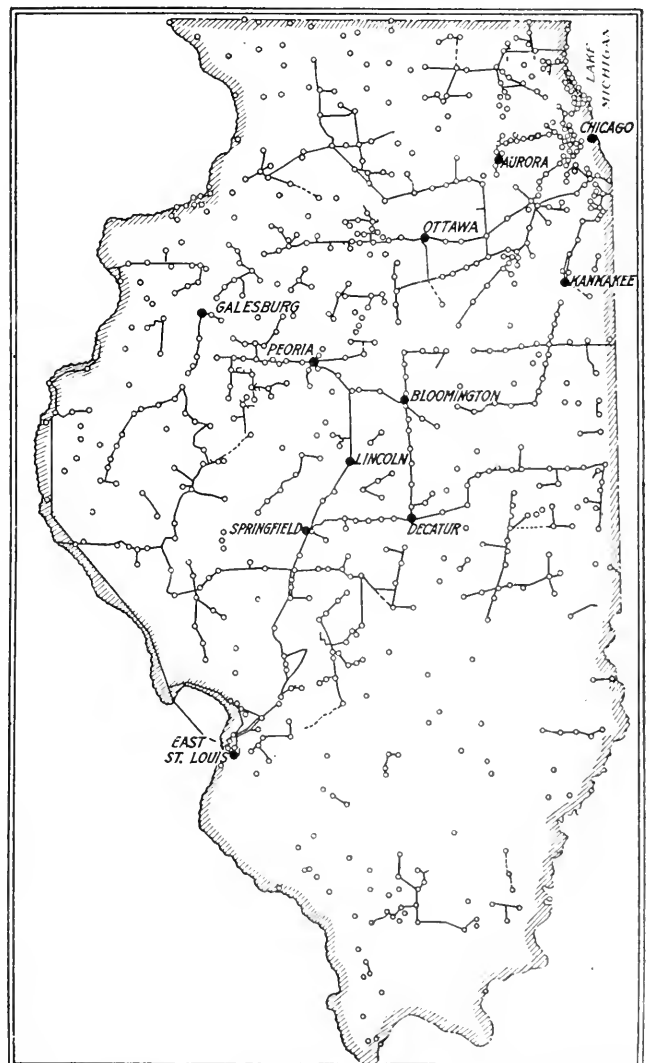

THE map printed herewith shows the transmission lines owned by twenty-eight companies within Illinois. A considerable number of these companies are already interconnected for exchanging service, when conditions make the interchange of power advisable.

There are several connections between systems in Illinois and those in neighboring states. The Central Illinois Utilities Company has a connection with the system of the Interstate Public Utilities Company of Indiana. This connection, it is understood, is used only for emergency purposes on account of the fact that the load characteristics of the two systems are very much alike.

The East St. Louis Light & Power Company has a connection with the Union Electric Light & Power Company of St. Louis by means of a submarine cable under the Mississippi River. The contract covering this service was authorized by the Illinois Public Utilities Commission within the last few months. This connection is now in use and is mainly for the purpose of supplying emergency and peak service to the East St. Louis company from the plants of the Union Electric Light & Power Company.

The Mississippi River Power Company, with its plant on the Iowa side of the Mississippi River at Keokuk, transmits energy into Illinois, after which the line goes down the river to Halls, Ill., where a tap is taken off for a cement plant at Ilasco, Mo. Energy is then transmitted further down the river on the Illinois side and crosses just above St. Louis for the purpose of supplying the requirements in St. Louis. Energy is also supplied to Alton, East St. Louis and Belleville, Ill., through

the system of the East St. Louis & Suburban Railway Company, which operates in connection with steam plants at Alton and East St. Louis.

INTERCONNECTED TRANSMISSION LINES OF ILLINOIS

STATION & OPERATING PRACTICE

A Department Devoted to Problems of Installation, Operation and Maintenance of Equipment for Economical Generation and Distribution of Electrical Energy

HOW USE OF SPECIAL LAMPS WAS AVOIDED

Some Available Auto-Transformers Were Connected So as to Operate 6-Amp. Lamps from 4-Amp. Circuit

Apparatus for 4-amp. series alternating-current circuits is not so extensively used as formerly, installations of this character having been largely superseded by 6.6-amp. or 7.5-amp. circuits. In one instance a company having a 4-amp. circuit feeding a number of 40-cp. municipal lamps desired to add half a dozen 250-cp. gas-filled units to the circuit. As 250-cp., 6.6-amp. lamps were standard elsewhere on the system, it was not considered advisable to secure special 4-amp. lamps. Consequently several small auto-transformers which had been in operation feeding 20-amp., 600-cp. or 15-amp., 400-cp. lamps from 6.6-amp. circuits were utilized. They were self-contained in the type of pendant unit that was to be used. Tests were made on one of these auto-transformers with a 4-amp. primary current and no difficulty was found in locating a combination of leads which with this circuit current would give 6.6 amp. through a 250-cp. lamp. Utilization of this equipment permitted the use of standard lamps, and the arrangement has given perfect satisfaction ever since.

EFFECT OF POOR COAL ON PLANT EFFICIENCY

Increased Price Combined with Poorer Grade of Coal Brings About a Large Increase in the Unit Cost of Power

The effect of poor-quality coal on the performance of the Manchester Street turbine plant of the Rhode Island Company, Providence, was set forth at a recent meeting of the New England Street Railway Club by W. C. Slade, superintendent of power and lines. This station contains, besides other smaller equipment, two 15,000-kw. turbines delivering 25-cycle energy to the station buses. Its 1917 output was 73,492,300 kw.-hr., and the average price of coal is now over \$8.35 per ton alongside, excluding demurrage charges. Up to date the company has received nearly \$6,000 in demurrage bills on the last eleven boats, on which about two-thirds was incurred on the loading end.

From 8.5 cents per ton the discharging costs have advanced to 23 cents. This is due to the fact that the company is obliged to discharge boats on overtime work to avoid the high demurrage charges, and to-day coal passers along the Providence waterfront are receiving 50 cents per hour straight time, 65 cents for overtime, and 75 cents per hour on Sundays and holidays. The majority of these men are unable to read or write or to speak or understand English.

Prior to the time when coal-mining conditions be-

came abnormal and transportation facilities demoralized, the company usually burned New River or Pocahontas, with an average of about 14,900 B.t.u. per lb. Even the same grade of coal, owing evidently to poorer preparation at the mines and at a later time possibly to the pooling of the coal supplies by the government, gave a noticeably lower average B.t.u. on analysis. The spot cargoes purchased outside, consisting mainly of Pennsylvania coals, were in some instances of very poor quality. Of the coal placed in the yard storage, 35 per cent showed a heat value under 14,500 B.t.u., and 46 per cent under 14,750 B.t.u. In fact, 21 per cent was under 14,000 B.t.u. Owing to the deterioration of the coal in storage before it was consumed under the boilers, the average B.t.u. value of the coal as fired was not over 14,300 B.t.u. The effect of the quality of the coal was reflected directly into the cost of operation and was seen in increased boiler-room maintenance.

DATA ON COAL FACTOR OF PLANTS

Period	MANCHESTER STREET STATION		ROCKLAND STATION	
	Lb. Coal	Per Cent Increase	Lb. Coal	Per Cent Increase
Year ended June 30, 1916.....	2.28	3.49
Six months ended Dec. 31, 1916...	2.38	4.4	3.78	8.3
Year ended Dec. 31, 1917.....	2.69	18.0	3.99	14.3

The net result was to raise the unit cost of power for the year 1917 by 106 per cent compared with the 1916 fiscal year.

The coal factors for the Manchester Street station and also for the small engine-driven plant of the company at Rockland, R. I., have been growing worse since 1916, which was the last fiscal year not affected materially by the advancing costs of fuel, material and labor.

The unusually high coal factor of the turbine plant in 1917 was due to a combination of operating conditions requiring a large number of banked hours on standby boilers not used in 1916, together with the necessity of burning a considerable amount of inferior coal, as well as coal damaged by spontaneous combustion. The performance will not be repeated in 1918. Under favorable conditions the plant was operating for a part of January, 1918, at 2.13 lb. (0.96 kg.). The decrease in economy at both turbine and engine plants has been of the same relative order.

The cost of power at Manchester Street increased 23.4 per cent for the six months' period above tabulated and 106 per cent for the following year. At the small Rockland plant the increases were 31.8 per cent and 73.5 per cent. While the cost was due partly to the abnormally high price of coal, it was partly due to the poor quality of coal available. In the year 1917 steam-

plant maintenance at Manchester Street increased 75 per cent compared with the fiscal year 1916, and other maintenance charges increased only 13 per cent. The increase in the cost of fuel as fired was 132 per cent and raised the fuel charge in 1917 to as much as 83 per cent of the total maintenance and operating costs. Wages advanced 30 per cent and all other operating charges 25 per cent. The kilowatt-hours delivered increased only 4.9 per cent and the pounds of coal per kilowatt-hour 18 per cent. Mr. Slade expressed the belief that many small railway plants ought to be shut down and that electrical energy should be purchased from a central-station system.

MOTOR CONTROL ELIMINATES FUEL WASTE IN SUGAR MILL

Automatic Control Allows Power Input of Sugar Mills to Vary Directly as the Output, and Refuse Fuel Is Sufficient at All Times

A new system of electric drive and control has been designed and installed in a cane-crushing mill in Central Cunagua, Cuba, by the General Electric Company. The mill had previously been operated by variable-speed induction motors with manual speed control through a secondary motor reactance. When the mill operated at reduced speed it was found that the power input to the motors was the same as that required at full load. Hence, as fuel is supplied from refuse cane,

ENERGY INPUT MADE PROPORTIONAL TO OUTPUT OF MILL BY USE OF CONTROL APPARATUS

an adequate supply was not available when the mill ran at reduced output. Additional coal or wood for fuel was therefore needed at various times.

The new system installed provides for automatic control of the crushing rolls, for relative speed adjustments and operation of a variable-speed turbine-generator to vary the output of the mill. Each motor in the mill is served from an individual control panel shown in the accompanying illustration. This panel controls the speed of the motor by means of a balanced voltage relay and through a three-phase motor-operated rheostat. The several motors driving individual rolls composing a mill or tandem are operated from a turbine independent of the sugar house, and therefore speed changes of the mill will not affect the operation of motor-driven pumps and miscellaneous machines.

The equipment was furnished by the Westinghouse Electric & Manufacturing Company.

SHALL TRANSFORMERS BE BANKED IN A DISTRIBUTION SYSTEM?

Opinion and Practice of Ohio Operating Distribution Engineers Brought Out in Discussion of a Paper on Interconnecting Plan

At a recent meeting of the transmission and distribution engineers of the Ohio Electric Light Association M. E. Grah of the Toledo Railways & Light Company presented a paper entitled "Shall Transformers Be Banked in a Distribution System?" In his paper the author pointed out economies that can be effected by operating certain parts of a system in this manner and expressed the opinion that the plan should be applied only after a detailed study of the conditions existing in each case had been made and a design worked out to meet those conditions.

In the discussion W. E. Beatty of the Union Gas & Electric Company, Cincinnati, Ohio, said that the practice of banking transformers had been practically abandoned by his company because of the obstacles encountered and the greater hazards produced during adverse conditions, such as those presented by storms. Furthermore, when several transformers had been banked together it was difficult to re-fuse the transformers, especially if one or two had been put out of service by the storm.

G. M. Miller of the Louisville (Ky.) Gas & Electric Company outlined a plan of banking which necessitated the fusing of branch lines where they connect with main lines. The branch lines are connected solidly to the transformers, whether one or more in number. The primary fuse used at the main line was designed to carry 200 per cent of the total rating of transformers connected to the branch circuit. Lightning arresters were utilized to protect each transformer installation. The secondary system was grounded inside each house ahead of the main-line switch. Mr. Miller stated that they had not experienced any difficulty with the transformers burning out owing to the high degree of fusing used in the branch.

B. L. Chase of the Columbus (Ohio) Railway, Power & Light Company said that banking transformers and connecting the secondaries solidly therewith induced a dangerous condition. For instance, even if the primary fuses used for isolating the individual transformer should blow, thereby disconnecting the primary from the transformer, the transformer would still be "hot" because the secondary connection of the other transformer would act as a feeding point. This often deceived the lineman sent to clear the fault and sometimes caused a serious accident. In addition, the damaged fuse cut-outs might remain "alive" and cause trouble in the whole system.

I. L. Kentish-Rankin of the *Electrical Review* expressed the opinion that transformers should be banked because of the increased efficiency, better regulation and the lesser cost per kilovolt-ampere and because of the possible use of larger capacities in each unit.

J. W. Bryant of the Wagner Electric Company, Cincinnati, Ohio, pointed out that the continuity of service demanded to-day will not permit the continued use of the old scheme of banking.

M. H. Wagner of the Dayton (Ohio) Power & Light Company emphasized the importance of safety to linemen and pointed out that the present-day linemen are

not of the same caliber as the old-type linemen. In his opinion the old method of banking transformers and connecting secondaries in solidly should be abandoned. When the system to be rebuilt is in a fairly congested district where the diversity is regular, then installing secondary fuses at the neutral point in the secondaries may be advisable.

Concluding the discussion, Mr. Grah pointed out the necessity of using transformers having similar characteristics and the same rating in a banked system. He added that fusing the neutral point in the secondary presents two difficulties—first, that of obtaining the true neutral point; second, that of obtaining a suitable secondary fuse.

SIMPLE ARRANGEMENT FOR THE TESTING OF D.-C. METERS

Resistance and Battery Loads Can Be Adjusted Over Wide Range—Board Can Be Built for Any Rating Desired

BY J. M. M'CLURG

Meter Department, Scranton (Pa.) Electric Company.

The accompanying diagram shows a simple arrangement for testing both large and small direct-current meters that can be adapted to any size load. The board has two distinct loads, one being on 110-volt direct

CONNECTIONS FOR TESTING LARGE AND SMALL DIRECT-CURRENT METERS

current with resistance for a load up to $32\frac{1}{2}$ amp. The other load is a storage battery and depends on the size of battery used. The load is controlled by a double-pole, double-throw knife switch, making it possible to leave the triple-pole switch in circuit during the test and changing over from full load to light load by using the double-pole, double-throw switch. This economizes time, the tester setting the load he desires by the small single-pole, single-throw switches for light load and a carbon rheostat in the battery circuit for full load, thereby leaving only one switch to operate during the test.

A carbon rheostat is mounted under the table, the carbons being separated into sections by brass plates. This provides for the cutting out of sections of carbon plates if the resistance is too great, the brass plates being connected to the binding posts marked A. A

copper rod slides through the binding posts, so as to short-circuit part or all of the carbon rheostat as the test requires. This is a convenient carbon rheostat that can be used for light or heavy loads. The board can be built for any desired capacity by increasing the sizes of the load, terminals, circuits, etc.

NON-SWEATING LINING FOR ROOFS

Waterproof Concrete Slabs, Asbestos Felt, Gypsum and Wood Fiber Employed

A form of roof construction was employed in the recently completed power plant at Columbus, Ohio, that may be found suitable in other central stations. The roof for the boiler room consists of concrete slab, waterproofed with three-ply J-M asbestos felt laid in asphalt. The turbine-room roof is similar, except that slabs made of a composition of gypsum and wood fiber are used, this construction being resorted to in order to avoid the possibility of condensation forming on the under side of the roof. The concrete slabs for roof and floors are supported by asbestos-protected corrugated metal with reinforcing fabric. The slabs are flat in both cases, being $2\frac{1}{4}$ in. (5.71 cm.) thick for the roof and 4 in. (10.16 cm.) thick for the floor.

RESISTOR MOUNTING THAT AFFORDS GOOD VENTILATION

Grids Supported Overhead on Projecting Floor Beams to Facilitate Rapid Dissipation of Heat Are Found Advantageous

In a New England shop where circuit breakers are tested frequently the resistors which are used to limit the load are mounted on extended wooden joists, as shown in the illustration. By so doing it was possible to keep the resistors off the floor and at the same time

MOUNTING PERMITS CIRCULATION OF AIR THROUGH GRIDS

facilitate the dissipation of heat generated in the grids. Since the resistors are not closed in on any side the air has free access to the grids. The open wiring run to the resistors is carried underneath the joists in porcelain cleats.

RATE INCREASES JUSTIFIED IN THE LANGUAGE OF LABOR

Explanation of the Public Utility Rate Situation
Written from the Workingman's Point of View
That May Be Used as Copy for Local Papers

An Indianapolis publication devoted to the interest of organized labor and called the *Union* has been devoting considerable space to public utility topics as they affect labor. The editors of this paper, having the point of view of labor, are able to present the case of the public utilities in language and in a spirit that the workingman can comprehend and is in sympathy with. The following editorial from the *Union* is republished herewith with the thought that it may assist public utility managers in formulating the sort of arguments they need when rate increases are applied for. It might also provide the basis of an article for local newspapers in quest of copy:

A friend of the *Union* protests against the tone and subject matter of our article on the conservation of the public utilities. He does not deny that the facts are as stated and that there is a distinct prospect of the companies administering to the public going to the wall, but he says that will be good for the soul of them. "Moreover," says he, "let them stand by their contracts with the people from whom they derive their franchise rights. They have agreed to deliver

operating companies to go into liquidation, which is the apparent alternative.

The *Union* has no brief for these public corporations, but, standing as it does for justice for the man who has labor to sell, it must also stand for justice to those who have the contracts to sell those commodities without which the modern community cannot exist. The workingman could not prosper to-day on the wages of three years ago—he could not exist in the mass; and the same changing conditions that have made for the high cost of living in the home have enormously increased the standards of costs for all business. We must adapt all prices, whether for public service or for bread or cheese, to the new standards.

MAKING IT EASY FOR THE CUSTOMER TO SAY "YES"

Way in Which the Advertising Department of One
Central-Station Company Changed the
Stereotyped Return Post Card

The average return post card used in central-station companies smacks more or less of legal phraseology. It usually contains a formal statement that the person signing the card is interested in the proposition and a still more formal statement that signing the card places the signer under no obligation to the company. That is the sort of card the new-business manager

U have been saying in your letters just about as much as I can stand without asking you to submit some proof about wiring my home. I may or may not give you my business, but I should like you to come and give me an estimate. Perhaps you can wire my home after I know what it will cost. Of course, I understand this doesn't obligate me.

Name _____
Address _____

YES

You may send your representative to see me about Electric Light in my home. I take your word for it that this service will not obligate me in any way.

THREE POST CARDS WHICH GET AWAY FROM THE STEREOTYPED PHRASEOLOGY

certain service for a certain price; it is up to them to do it. If an individual having a contract loses money he has to stand the loss and go bankrupt if necessary. Well, the public utility companies have the wrong end of a losing contract, that's all."

But it isn't all. If John Smith has a private contract and goes broke on it by reason of a changing labor or material market that is tough on John Smith, but it does not disturb the community. But if the water or gas or electric light or traction company goes broke and stops doing business that touches us all. As a matter of public policy we must see to it that the public service in these commodities is maintained; whereas, as a matter of public policy, the fate of John Smith is not to be considered. As a body we could not step in and save John Smith from the evils that lie in a changing market; but the people may and should take such steps as may be necessary to protect themselves and their families and the city from the consequences that must follow on the suspension of any one or more of the public utilities companies.

And it would appear that it would be cheaper and more practicable to change the fixed rate of compensation for the services rendered where it is required than to permit the

fondly hopes a large number of people will enthusiastically sign and return. It is a surprising truth that some persons do sign them and send them in, but it has been truthfully said that such persons must be very much interested in things electrical. There is nothing on the card to inspire enthusiasm. Its legal phraseology makes its reader involuntarily suspicious, of just what it may commit him to, and in nine cases out of ten it is thrown aside or dropped into a convenient waste-paper basket.

Realizing this situation and feeling a desire to make all of its advertising as human as possible, the Minneapolis General Electric Company has printed some return post cards that are different. They are designed to make it easy for the prospective customer to say "yes." Three of them are reproduced herewith. They were one of the features of an exceptionally successful house-wiring campaign which the company has been running continuously for many months.

CONTINUOUS METER-READING IS A WAR-MEASURE PLAN

Necessity for Distribution of Work as Equally as Possible on Readers and Office Staff That Are Left

On Feb. 1 the Beverly (Mass.) Gas & Electric Company adopted the continuous system of reading meters and mailing bills, the new plan being adopted owing to conditions created by the war and the necessity for distributing the work as equally as possible for the meter readers and office staff. Under the old plan the bills were read between the fifteenth and twentieth of each month and were mailed on the first of the month.

The city, which has a population of around 20,000, has been divided into about twenty-four districts. The gas and electric meters in the first district are read on the first working day of each month and bills mailed two days later. The meters in the second district are read on the second working day of each month and bills mailed two days later, the meters in the third district on the third day, and so on. Ten days from the date of mailing bill are allowed in which to secure the discount for prompt payment. Discount dates are plainly stamped on all bills.

VIGOROUS CAMPAIGN ON ELECTRIC TRUCKS IN CHICAGO

Thirty-five of These Trucks Have Been Sold—A New Method of Charging for Garage Service Is Developed

Since last fall, when the Commonwealth Edison Company entered into an active campaign of advertising and special sales efforts to promote the electric truck business, thirty-five trucks of all sizes have been sold in Chicago. These truck sales were due in part to the company's efforts and in part to the hard work of representatives of the truck manufacturers. The trucks which have been sold were made by the Ward company, the Walker Commercial Truck Company of America and the Couple Gear company. The prospects for further business are exceptionally bright at this time, some twenty-five or thirty companies having under consideration the purchase of from one to twenty trucks.

The company's complete maintenance plan for electric trucks was described in earlier issues of the ELECTRICAL WORLD (June 2, 1917, page 1080, and Dec. 29, 1917, page 1247) and is briefly as follows: A customer by paying a flat charge per month gets everything his transportation service requires except liability insurance and the services of a driver. Ordinary repairs, tires, battery renewal and charging, washing, garaging and painting are all covered by the contract. The only stipulation is that the contracting party must start with new electric trucks. Energy taken from the company's direct-current substations is distributed to fifty-eight charging positions in the two rooms into which the one-story building is divided. Each circuit, in addition to carrying the usual switching equipment, also has an individual rheostat and meter. The rating of most of the circuits is 100 amp., but some circuits to carry 200 amp. are installed for boosting.

Besides its plan for maintenance, the company now

offers truck users an unusual garaging proposition. The trucks sold under this agreement are kept in the building which was built for housing trucks under the general maintenance plan. A feature of the measured garaging service which the company has recently started to offer is that it does not charge for truck storage on the basis of the truck ratings in tons, as is the usual plan. Instead it charges for the floor space occupied by the truck at a fixed price per square foot occupied. The price at present is 25 cents per square foot on the over-all dimensions of the truck. This charge includes, in addition to garaging, oiling, washing, placing the batteries on charge, flushing the batteries, keeping records and general inspection. In addition to this the company sells these truck users electricity at 5 cents per kilowatt-hour. This plan of charging for garage service is thought to be an exceptionally just one, as there are many 2-ton trucks which occupy as much space as some 5-ton trucks. This is particularly true where the truck body is designed for hauling waste paper or other very light and bulky products. All trucks taken into the company's garage on this plan have their batteries charged according to the rules approved by the local section of the Electric Vehicle Association, and records on the trucks are also kept according to the approved practice laid down by the same body.

Truck users in the city are finding this plan a very practicable one, and considerable business is expected to develop from it for the Commonwealth Edison Company as well as for the manufacturers of the trucks.

GETTING AFTER THE HIGH-RATE BUSINESS

Methods Adopted by Illinois Company for Taking New Business That Is Profitable and Does Not Require Additional Investment

The Public Service Company of Northern Illinois is among those utilities which believe it wise to seek additional income from business that does not require capital investment. John G. Learned, assistant to vice-president of the company, in commenting upon the company's efforts along this line, stated it as his belief that this can be accomplished by more completely equipping the home. Moreover, the additional business secured in this fashion is usually business that comes to the central-station company on the higher steps of its rate schedule.

With these facts in mind, the Public Service Company of Northern Illinois has published special advertising matter on the subject which was prepared at the company's suggestion by the Harvey Hubbell Company. These folders are being distributed among all of the public service company's residential customers. The pamphlets go somewhat further than the ordinary literature of this sort, for they not only show the advantage of having a baseboard receptacle but also point out the value of making this receptacle do double duty by installing a duplex unit. The company has arranged the following terms of payment for customers who wish to install additional outlets: Where the amount is less than \$6, cash thirty days; where the amount is \$6 to \$12, six equal monthly payments; where the amount is \$12 or over, twelve equal monthly payments.

TECHNICAL THEORY & PRACTICE

Including a Digest of Important Articles Appearing in
the Scientific and Engineering Press
of the World

Generators, Motors and Transformers

Notes on the Design of Electromagnetic Machines.—STANLEY PARKER SMITH.—Magnetic leakage of the non-salient pole rotor consists essentially of slot leakage, says the author. The effect of slot leakage is to divert flux which would otherwise pass radially through each tooth, so that the lines of induction assume an oblique direction sloping away from the pole center. If magnetic wedges are used—e.g., cast iron—the slot leakage is considerable, but with non-magnetic wedges the effect of slot leakage is usually less than that of end-bell leakage. Bronze wedges are used. The article also dwells on excitation and the determination of the flux per pole and touches on other considerations. The author says that generally the reluctance of cores has no effect on the flux distribution in the gap. The excitation needed to send the current through the stator winding when short-circuited is due to the inductance and reaction of the stator winding.—*London Electrician*, Feb. 15 and 22, 1918.

Alternating-Current Single-Phase Motors.—GORDON FOX.—In this article the author explains the principles underlying the operation of different types of single-phase motors. The advantages and disadvantages of different forms of construction are discussed. Characteristic curves and connections for several kinds of motors are presented.—*Railway Electrical Engineer*, March, 1916.

Generation, Transmission and Distribution

Ninety-five-Thousand-Kilowatt Addition to Northwest Station.—The Commonwealth Edison Company of Chicago is completing the installation at its Northwest station of three additional turbo-generators of an aggregate capacity of 95,000 kw. Two are of the compound reaction type and the third is an impulse machine of new design. One of each type is now in operation, and the second compound machine is in course of erection. At the turbine throttle steam is supplied at a pressure of 230 lb. gage and 200 deg. superheat.—*Power*, March 12, 1918.

Standardized Flexible Distributing Systems in Industrial Plants.—BASSETT JONES.—The author has worked out a system for determining the power requirements of industrial plants in advance of construction, the method being based on a relationship between projected tool area, manufacturing area and total square feet of floor area. The study of this subject was undertaken in connection with the electrical distribution for a new factory building of the Sprague Electric Works, General Electric Company. The author points out that all equipment employed in the generation and distribution of electric power has practically been standardized, except distribution systems in industrial buildings, and he shows that standardization here is equally practicable and desirable. In any industrial plant flexibility in distribution to take care of

frequent changes in machine tool layout is of the utmost importance.—*General Electric Review*, March, 1918.

Interconnection of Electricity Supply Undertakings in the West of Scotland.—Some details of a report issued by the West of Scotland committee for the interconnection of electricity supply undertakings are given in this article. In order to facilitate investigations as to the possibility of and advantages to be derived from interconnection, the local authorities and companies operating electricity supply companies have been arranged in groups according to their geographical proximity and similarity of supply systems. Conditions that make it difficult or practicable to connect the systems of each group are outlined. Load curves of the individual corporations as well as composite load curves which would represent the total load if the systems were interconnected are given. Reviewing the subject of interconnection as a whole, the committee has come to the conclusion that financial benefit would be derived from linking up some of the systems for the purpose of interchange of energy. In some of the groups considered the economy of week-end supply from one station might be doubtful, but the committee is of the opinion that considerable economy could be effected in many of these cases by a supply in bulk from the larger to the smaller stations.—*London Electrician*, Jan. 15, 1918.

National Electricity Supply in England.—Comments of a power station engineer on the basis for the interim report issued by the coal conservation sub-committee to the Minister of Reconstruction (British) are presented in this continued article. The author, whose name is not mentioned, says that the report is undoubtedly strong in the main features of its findings, but the facts and figures on which many of the arguments are based are lamentably weak or absolutely inaccurate. He then goes on to discuss some of the points. Among one of the things he emphasizes is that if power plants were rehabilitated so that the fuel consumption of 5 lb. per horsepower-hour was reduced to 1.5 lb. per horsepower-hour, practically all existing power plants would have to be scrapped and new super-stations containing generating units rated at 30,000 kw. and 50,000 kw. would have to be provided instead.—*London Electrical Review*, Feb. 22, 1918.

Rapid Growth of Southern Canada Power Company.—Charts given show the territory served by the Southern Canada Power Company, and information is included regarding the extent of the company's operation and its past history, with a few words regarding future developments.—*Canadian Electrical News*, Feb. 1, 1918.

Traction

Electrical Signaling and Control on Railways.—C. M. JACOBS.—After outlining the cardinal requirements of railway signaling apparatus, the author takes up the

subject of track circuits, automatic train control, gravity-sorting sidings, single-line working, power for electric signaling and limitation of electric signaling methods. He points out that in order that track circuits may be reliable they should be adjusted for minimum train shunts at infinite ballast 5, 10 and 20 ohms respectively. By means of curves he shows that the problem is to reduce the fraction of the unshunted relay current which passes through the relay when it is shunted by a predetermined minimum ballast resistance to a lower fraction known as the armature release current, which is usually 60 per cent of the minimum pick-up current. Tables are given giving track-circuit factors and ratio of armature release shunt to minimum ballast shunt for various minimum pick-up currents. Some requirements of automatic train control are outlined and reference is made to the equipment used by the Great Western Railway. A system for operating the points of a gravity-sorting siding used on the Eastern Railway of France is described, together with an old British method of working single lines by means of tokens. In regard to power for signaling purposes, the author points out that in large centers, at any rate, it should be more economical to derive the energy for operating signals from a central battery than from individual batteries with limited output.—*Journal of the Institution of Electrical Engineers* (British), February, 1918.

Power Distribution for the Montreal Tramways.—Standardization combined with flexibility and the effective utilization of existing equipment were primary design considerations in the rehabilitation of the power system of this company.—*Electric Railway Journal*, March 9, 1918.

Electrophysics and Magnetism

Electrolysis of Underground Structures.—SAMUEL S. WYER.—A digest of publications of the Bureau of Standards on the electrolysis of underground structures caused by the disintegrating action of stray electric currents from electric railways has been compiled by the author. Among the subjects covered are cause and economic importance of electrolysis troubles, electrolysis surveys, corrosion principles, relation of soil characteristics to electrolysis, electrolysis of concrete, current leakage, mitigation applicable to pipes and railway negative return, and electrolysis regulations.—*Bureau of Standards Publication*.

Telegraphy, Telephony and Signals

Open-Circuit Oscillators as Receivers.—A detector circuit is described in which a three-electrode vacuum-valve detector is connected to the free end of a wireless telegraph aerial while a tuning coil is inserted at the earth end to tune the aerial circuit to resonance or to impress the maximum potential on the grid of the vacuum valve for a given group of incoming oscillations.—*Wireless Age*, January, 1918.

Production of Continuous Waves by Spark Discharger.—This article describes briefly a system for generating high-frequency alternating current which has been developed by Riccardo Arno. By means of the arrangement shown in the article the inventor states that he is able to secure more than 30,000 spark discharges per second, resulting in a practically continuous flow of high-frequency current in the wireless aerial. The Arno apparatus is not limited to the use

of the high-frequency alternator, any type of generators heretofore employed in connection with radio work being suitable.—*Wireless Age*, January, 1918.

Electrochemistry and Batteries

Dry Cells and Wet Batteries.—WILLIAM J. HEEDMAN.—The author discusses the primary and secondary types of cells, two classes of primary cells, general construction of dry cells and their care, closed circuit cells and their maintenance.—*Telephone*, March 9, 1918.

Installations, Systems and Appliances

Electric Cargo Winches.—E. F. WHITNEY.—This article dwells on the requirements which have to be met by motors in operating cargo winches. Some electrical equipment suitable for this service is described and the superiority of its operation is discussed in terms of reliability, speed, control, cost and efficiency.—*General Electric Review*, February, 1918.

Electricity in Logging and Saw Mills.—E. H. HORSTKOTTE.—A particularly satisfactory arrangement of power equipment in a large lumber mill in the West is described. This mill burns sawdust in the boilers to operate electric generators which are tied in with the power system of a local public utility for mutual exchange of energy when conditions require.—*General Electric Review*, February, 1918.

Miscellaneous

Notes on Electric Welding.—CAPT. JAMES CALDWELL.—The author gives a résumé of the chief methods of welding, beginning with resistance welding. He goes on to state that this is a form of electric welding which is the closest approach to original smith welding. Butt welding is applicable to the welding of rods, bars, etc., transverse to the length of the pieces, and spot welding is most commonly adopted in England to unite sheets or thin plates where a continuous weld or joint is not required. Seam welding is an extension of spot welding, applicable to comparatively thin sheet-work. With the carbon-arc method of welding 90 volts and 50 amp. to 500 amp. are required, according to the size of the work. The author explains that in one process involving the use of coated metal electrodes the covering is made of fireproof material so that as the metal electrode is melted it is directed on the work being welded. In another process the sleeve or covering on the metal electrode melts, forming a flux that protects the added metal from oxidation. The flux may contain constituents which have a chemical action on the fused metal.—*London Electrician*, Feb. 15, 1918.

The Boston Turbine Accident.—A detailed account of the wreck of a 35,000-kw. single-cylinder turbine at Boston. It seems that the deflection of the cast-iron diaphragm in the eighteenth stage, causing the diaphragm to rub the wheel and release the buckets, was the immediate cause of the accident. The question is raised whether it is not advisable to extend the use of steel to the large diaphragms in the lowest stages of these high-capacity machines. The opinion is advanced that if it is found that the cast iron is subject to frequent deflection, that the bond between the buckets and the disk and ring of the diaphragm soon weakens, or if these relatively thin disks are likely through any cause foreseen to be subjected to the stresses set up by centrifugal force imposed by accidentally revolving with the shaft, then steel seems advisable.—*Power*, March 19, 1918.

NEWS OF THE INDUSTRY

Chronicle of Important Events and General Activities in the Technical, Commercial and Manufacturing Fields

N. E. L. A. PLANS TO HAVE WAR-TIME CONVENTION

Executive Committee Decides to Hold Meeting Between May 15 and June 15, Probably in Central West, for Serious Business Only

The executive committee of the National Electric Light Association decided at a meeting in New York on March 22 to hold a strictly war convention this year. The convention will be held, according to the present program, at some time between the middle of May and the middle of June, and probably in some city of the Central West, although the latter point is not entirely settled. A Central Western city is favored for the reason that such a location will minimize railroad travel of delegates, and this is an important consideration bearing on the war. If possible, the sessions will be kept within two days. No arrangements are to be made for entertainment or for the reception of ladies this year, it is understood.

A convention committee to take charge of the affairs connected with the meeting is being formed. Walter Neumuller, New York Edison Company, will be chairman and T. C. Martin secretary.

The need for a war convention this year arises from two general conditions on which members are seeking information and advice to guide them in their operations: First, thorough knowledge of ways in which they may assist in winning the war; second, a better understanding of the methods by which they may meet the internal problems resulting from the war.

ELECTRICAL MEN CO-OPERATE IN SOUTHERN CALIFORNIA

The Spirit of Co-operation Dominates a Successful Gathering Held at Los Angeles to Further the Cause of Harmony

The new word "synergism" was defined and elucidated at a banquet in Los Angeles on March 15, when 350 electrical men gathered to fire the first gun in the California electrical co-operative campaign. At the Riverside convention of the Pacific Coast Section, N. E. L. A., held April, 1917, a desire was expressed for a more harmonious alignment of the various branches of the industry. As a result a liberal fund has been subscribed by central stations, manufacturers, jobbers, dealers and contractors so that constructive work may be done by trained men whose time will be spent in skillfully pointing the way for closer co-operation.

S. M. Kennedy, secretary and general agent of the Southern California Edison Company, was toastmaster at the Los Angeles banquet. Willis H. Booth, chairman of the board of the Edison Electric Appliance Company, spoke on "Reciprocation"; W. D'Arcy Ryan, illuminating engineer General Electric Company, on "Electrifica-

tion"; L. H. Newbert, chairman advisory committee California electrical co-operative campaign, on "Co-ordination"; G. E. Arbogast, president Southern California Contractors and Dealers, on "Affiliation"; H. F. Jackson, president Pacific Coast Section, N. E. L. A., on "Unification"; D. J. Butts, manager Western Electric Company, on "Co-operation"; Albert H. Elliott, secretary Pacific Coast Jobbers' Association, on "Synergism," and B. F. Pearson, general superintendent Southern California Edison Company, on "Synchronism."

The enthusiasm displayed left no room for doubt that the electrical men of California have reached a permanent basis of understanding, the object of which is the good of the industry, the elimination of friction and waste, scientific efficiency, better work and better service for the consumer, and all in a spirit of co-operation in peace and in war times. Patriotic feeling and a determination to support the men "over there" characterized the speeches and the singing. There is little doubt that this meeting marked an important advance and that in some respects it may be considered historical.

SEES GREAT EXPANSION FOR ELECTROCHEMICAL INDUSTRIES

Secretary Lane Wants Hydroelectric Developments Started to Care for Chemical Needs of Nation After the War

While testifying before the joint special water-power committee of the House of Representatives in Washington March 27 and discussing the so-called "administration water-power bill," now pending before the committee, Secretary Lane predicted a great expansion of the electrochemical industries of the United States.

"We ought to appreciate more fully now," Secretary Lane said, "that after this war is over there will be the necessity of larger electrical development than we have ever had before in connection with the chemical industries of the United States."

Secretary Lane said that in the United States we are merely beginning to understand what electricity can do and what can be done with very high-power electrical establishments. "We have never been a chemical nation," the secretary pointed out, "and that side of our scientific development has been overlooked."

"It is quite manifest to me that there has got to be very large electrical development if we are going to have the largest uses made of our development along lines of chemistry, and perhaps the best sphere for a young man for the next twenty-five years will be as an electrochemical engineer in the United States. The water powers ought to be put into use now not only with the idea of taking care of plants that will be commercially successful propositions but with the purpose of experimenting and discovering what can be done."

Associated Manufacturers' War-Time Meeting

Proceedings Curtailed on Account of the War, but Great Work of the Year Is Reviewed and Plans for Development and Study of the Tariff Are Completed

—A. W. Berresford Is Elected President

H. B. CROUSE,
Retiring President

A. W. BERRESFORD,
Elected President

B. E. SALISBURY,
Elected Vice-President

J. W. PERRY,
Re-elected Treasurer

CHARLES E. DUSTIN,
Re-elected General Secretary

CURTAINED on account of the war, the third annual meeting of the Associated Manufacturers of Electrical Supplies, at Delmonico's, New York, on March 21, was nevertheless full of strong indications of progress and constructive promise for the future. Outside of the general program, the business session included as unusual features a discussion on the subjects of international trade conditions and trade acceptances.

H. B. Crouse, Crouse-Hinds Company, the president, spoke briefly in calling the meeting to order at 2:30 p. m. "The year's work," he said, "has shown clearly that we all know what this association is, and we are all using it and working hard for it."

Mr. Crouse added that it had been very gratifying as president to see how everybody was willing to help. The work had been done with a will, and as a result a great deal had been accomplished.

REPORT OF MR. DUSTIN

Charles E. Dustin, the general secretary, reviewed generally some of the lines of activity of the last year. The membership has shown a very satisfactory increase. Twenty-two new companies have affiliated, and while of course some companies have dropped out, it has not been through lack of faith in the value of the association, but by reason of consolidation with other member companies, in some instances, and in others because the particular products manufactured did not seem to fit in properly with the scope of the work of the association.

The basis of all co-operative work, Mr. Dustin continued, is through the sections, each particular line of the industry having its own section and these sections being subdivided to cover every special device coming under the general section head. Early in June, 1915, only two sections had been formed. To-day there are twenty-one sections, all actively engaged in work of particular advantage to the section members and of general advantage to the electrical industry as a whole.

In almost every section committees have been appointed to work with the industry conference committees of the Underwriters' Laboratories, and much good has

resulted without any friction or opposition, and many perplexing problems of the past have been satisfactorily adjusted. The association has a representative on the electrical committee of the National Fire Protection Association.

The distribution of industrial statistics has been continued with great satisfaction to members of a number of the sections. This has included the compilation of statistics pertaining to products handled by the members, tabulation of sales, tabulation of costs, movement of tonnage, etc., all of which is considered to be of value to the members interested.

The standardization of product and devices, added Mr. Dustin, has been carried on heretofore through committees working in each individual section, but it has been found that by co-ordinating the work of these committees from the various sections interested better results could be accomplished in less time, and with this in view the various standardization committees from the analogous sections have formed an interlocking standardization committee. This committee meets to consider such common subjects as might seem advisable and to report such common findings to the respective sections represented. The various standards adopted in the association are now known as A. M. of E. S. standards, and are referred to as such by the Underwriters' Laboratories.

In speaking of the war service work, Mr. Dustin said that the year has been one of unusual activity, due in great measure to the war situation and the keen desire shown by every member in the association to co-operate to the limit of his facilities with the government bureaus in furnishing necessary material required for war purposes. To make the co-operation of the greatest value to the government, the General War Service Committee of the Electrical Manufacturing Industry was formed, with Robert K. Sheppard as chairman. Supplementing this committee are twenty-five group committees representing different lines within the manufacturing industry and completing an intensive organization which is available for government service.

"We have many and extensive plans for the coming year," said Mr. Dustin in conclusion, "all of which will be more or less contingent upon the war situation and the requirements of the government. The association is ever broadening in its work, and we feel that we are starting on another successful year, which cannot but be of advantage to the members individually and the industry as a whole."

In the absence of Charles Blizzard, chairman of the finance committee, the report of that committee was read by Mr. Dustin. Commenting on the report, Mr. House said that the plans for the coming year are well laid, and he indicated that a membership drive will be made. The advantages of membership have proved to be of such value to those who are in the association that the results accomplished will be laid before others in the industry. Although the percentage of representation in the association is large, it is believed that better work can be done if it is made still greater, and that the

SERVICE FLAG FOR EMPLOYEES OF MEMBER COMPANIES OF THE ASSOCIATED MANUFACTURERS OF ELECTRICAL SUPPLIES

benefits of closer co-operation will be realized in substantial measure by both new and old members.

STUDY OF INTERNATIONAL TRADE

John J. Gibson, chairman international trade committee, spoke at length of the work which is being undertaken. Mr. Gibson said in part:

Your international trade committee feels that it has a message to deliver which is of the greatest importance to every member. The rôle of the prophet of evil is not a very pleasant one. He that croaks a dismal song of warning can hardly expect to be as entertaining as he who pours a sparkling wine of promise, but your committee has tried to mix in a little promise with the warning and hopes the mixture will be more palatable.

If you knew a man who was the father of a large family and who lived in a frame house which was full of expensive furniture and rugs, who traveled a great deal and who owned a great deal in automobiles and who carried life insurance, accident insurance or fire insurance, what would you think of him?

If you knew of a community somewhere where every one lived in a frame house and where there was no fire department, nor any locks on the doors, what would you think of the people who lived there?

Now, before you hastily indulge in criticism of the stupidity of such people, let me remind you that the electrical industry to-day stands in exactly that position in respect to the tariff.

This committee was created as the result of a discussion on this subject which came up at our last annual meeting.

It was several months before we got under way after being appointed on account of the summer coming upon us, but since last fall the committee has been quite active. At least, we have been on the job long enough to learn one thing, and that is that in this great industry, through the whole length and breadth of it, from top to bottom, there is not a single man that could be called an expert on tariff. Not a single man! That is a very strong statement, but it is true. Not even the biggest companies in the business have a tariff expert. In past years, when tariff bills have been passed, at the eleventh hour and fifty-ninth minute there was an extended telephone conversation and possibly telegrams; two or three people hurried to Washington and appeared before a committee of Congress, with the result that to-day the electrical industry has no separate recognition in the tariff schedule of the existing bills. What are we going to do about it?

To-day the government is making an effort to put the regulation of tariff upon a business basis, to run it just as each of you run your business, and there has been, as you know, appointed a United States Tariff Commission for the sole purpose of collecting data with respect to conditions in every line of industry in this country; for the purpose of ascertaining what protection, if any, is needed and for the submission and furnishing of that data to Congressional committees which are appointed for the purpose of drawing up new bills.

We must realize that not only does American industry need protection for its home market but it also must develop foreign trade, and while we might fall into the error of thinking we should build a Chinese wall around ourselves, still we must repress our impulses in that direction respecting our own market because such an action would invite retaliation upon the part of nations with whom we must do business, and thereby we should be excluded from their markets.

Your committee issued a number of letters to the various sections of this association in which it tried as clearly as possible to outline these facts and asked each section to appoint a sub-committee on the tariff and made a specific request that each of these committees report to the main committee an expression of the desires of each branch of the industry for protection after a proper study.

In seven or eight months—six, anyway—we have had just one reply. Does that indicate to your mind a lack of interest or not? Does it to your mind indicate rather a lack of knowledge? I am absolutely of the opinion that it is the latter. The further your committee has gone into this matter the further it has felt the necessity of expert advice and felt the necessity of detailed accurate information, carefully extracted from its source, carefully tabulated, carefully analyzed, which can be used under expert guidance to protect our interests, and that means, gentlemen, a great deal of work. It means a great deal more work than I can do, a great deal more than any one of our committee can do, a great deal more than any of you can do.

We are to-day suffering from the lack of preparation for war. Three or four years ago nobody would have dreamed of war. I am not going over that ground again; we have all had it burned in upon our minds. Three or four years from now we may be accused of being just as sound asleep on this question of protecting our home market and developing our foreign trade. The subject is one that justifies our going to some expense in connection with it, and your committee, having carefully considered the matter, has recommended in all earnestness that \$5,000 be appropriated to carry on the work of the committee during the coming fiscal year of the association; \$5,000 is a trifling sum for such vast interests as we represent to spend on this important subject.

Your committee has in a sense established relations with the Federal Tariff Commission, as the chairman of your committee called upon the Tariff Commission and was welcomed cordially. One of the commissioners who is especially interested in the study of conditions in various industries of the country is willing and has offered the services of the commission to help us. He will meet us more than half way in the preparation of a statement of facts in connection with our industry, and with the statement of facts we will have a better hearing in that court of final result to which we must appeal when a tariff bill is out,

namely, the proper committee of Congress when there is a bill pending.

Furthermore, at the present time the administration of the tariff law is full of pitfalls, full of loopholes, and for the protection of our own interests, if the old bill remains, we need expert advice on how to obtain the protection the present bill has for us.

President Crouse said that the nations in Europe are getting ready for the period after the war, and that the proposed study of tariff conditions may prove to be the greatest thing done by the association. The hardest thing to do with a hard proposition is to get started, and this the committee has done, he declared.

Following the recommendation of Mr. Gibson, the association decided enthusiastically to contribute the necessary funds to develop the work of study of the tariff. It is purposed to employ a tariff expert.

Charles L. Eidlitz, Metropolitan Electric Manufacturing Company, as chairman of a special committee on trade acceptances, made a report.

Much discussion followed. Mr. Eidlitz, President Crouse, W. T. Pringle, A. W. Berresford and W. W. Orr, Jr., assistant secretary National Association of Credit Men, took part.

President Crouse crystallized the discussion by saying that the majority are very much interested in trade acceptances and in favor of them.

As part of his report Mr. Eidlitz submitted a tentative resolution. Attention was also called to the resolution passed by the board of governors and published in the *ELECTRICAL WORLD* of March 16, 1918, page 578. The report of the special committee was referred to the board of governors.

NEW OFFICERS

R. E. Gallaher, New York Insulated Wire & Cable Company, chairman of the nominating committee, presented the names of the following to be voted on for governors for terms of three years from April 1, 1918: Charles Blizard, Electric Storage Battery Company; D. R. Bullen, General Electric Company; H. B. Crouse, Crouse-Hinds Company; H. R. Holmes, R. Thomas & Sons Company, and J. F. Kerlin, National Carbon Company, Inc. The secretary was directed to cast a ballot for the nominees.

After the meeting adjourned the governors met to elect officers. A. W. Berresford, Cutler-Hammer Manufacturing Company, was elected president; B. E. Salisbury, Pass & Seymour, Inc., vice-president; J. W. Perry, H. W. Johns-Manville Company, treasurer; Charles E. Dustin, general secretary.

At the annual banquet, held in the evening, also at Delmonico's, the thought of the war was dominant. President Crouse, who presided, gave a toast to "Our country and our President." The Manufacturers' Chorus of Bridgeport, Conn., composed of forty men, sang patriotic songs.

A great service flag was unfurled and dedicated eloquently by Robert K. Sheppard, Simplex Wire & Cable Company, chairman of the General War Service Committee of the Electrical Manufacturing Industry. It showed that 14,656 men have gone from member companies of the association to serve the nation. Since this total was compiled nearly 200 additional have been reported at the general offices of the association.

The address of the evening, a stirring account of personal experiences in the war area and of strong faith

in the outcome, was made by Major Donald Guthrie of the First Canadian Expeditionary Corps, now of the British Recruiting Mission.

WAR-TIME PROBLEMS ARE DISCUSSED IN WISCONSIN

President Lyons Points Out at Milwaukee Meeting the Needs of Utilities for Increased Rates and Comments on Conservation

Addresses dealing with problems affecting public utility rates were the feature of the tenth annual convention of the Wisconsin Electrical Association at Milwaukee on Wednesday and Thursday of this week.

President B. F. Lyons of Beloit sounded the keynote of the meeting in his address, pointing out the need of the utilities of Wisconsin for increased rates, and commenting briefly on the national measures of conservation, including the shutting down of isolated plants the interconnection of generating stations, and the passage of the daylight saving bill.

Edwin S. Mack of Milwaukee dealt with two important phases of public utility depreciation. The first of these was the method of treating depreciation reserve in Wisconsin. He contended that while the Wisconsin commission has included depreciation reserve in value it has not followed this out to the logical result that where the depreciated-value basis is used the return on the fund should go to the investor and not to the fund. The other phase of depreciation discussed dealt with the elements of depreciation reserve.

William J. Hagenah, basing his address on curves showing the range of commodity prices over a period dating back to 1817, predicted that few if any public utility managers in the room would live to see prices return to their pre-war level. For this reason he urged the closest co-operation between the utilities and the commissions that the utilities may be adjusted to the changed conditions under which they are operating and will be obliged to operate for many years.

Harold L. Geisse, secretary of the Railroad Commission of Wisconsin, read a paper showing public utility men how to prepare and to present rate cases to expedite their passage through the hands of the commission.

Speaking on the fuel situation, W. N. Fitzgerald, State Fuel Administrator of Wisconsin, declared that the coming winter would bring a national demand for increased production amounting to 100,000,000 tons. It will be possible to increase production only 50,000,000 tons. The rest will have to be saved by conservation measures. He urged public utilities to help.

The report of the rural service committee, of which A. C. Babson of Watertown is chairman, showed that rural service in the State increased 163 per cent in the last year, that there was a tendency toward greater customer density and toward a greater use of the connected load. In summarizing conditions for the last year the committee emphasized the necessity of getting a relatively high minimum charge and giving a low secondary energy rate.

The committee on taxation, of which C. S. Secheverell of Superior is chairman, repeated its assertions of former years that public utilities are discriminated against in the matter of taxes.

Other papers were to be delivered after this report was telegraphed to the *ELECTRICAL WORLD*.

OR THAT!

FOR EVERYONE
MUST DO HIS
DUTY!

ELECTRIC WELDING IN THE BUILDING OF SHIPS

Work of the Electrical Welding Committee of the
Emergency Fleet Corporation—Prof. Comfort
A. Adams Chairman of the Committee

The question of electric welding as applied to shipbuilding was brought to the attention of the standards committee of the American Institute of Electrical Engineers in August, 1917. At that time Prof. Comfort Adams, chairman of the standards committee, appointed a sub-committee to investigate the possibilities of electric welding in shipbuilding. This committee included representatives from the manufacturers of welding machinery, the classification societies (Lloyd's and the American Bureau of Shipbuilding), the Bureau of Standards, the Navy Department and shipbuilders. This sub-committee was adopted in September last by the general engineering committee of the Council of National Defense, and later (Feb. 21 of this year) by the Emergency Fleet Corporation, as its electrical welding committee.

Since the appointment of the original committee much time has been devoted to the investigation of the character of electric welds and to the development of necessary apparatus. As a result of this work the members of the committee became convinced that much time and material could be saved by the introduction of electric welding methods in shipbuilding. This conviction was gradually transmitted to responsible government officials, with the result, as above stated, that the committee was reorganized under and assigned a definite work by the Emergency Fleet Corporation.

An office has now been established in Room 716 of the Engineering Societies Building, New York, for conducting this work, which is to push the application of electric welding methods to shipbuilding as rapidly as possible.

The Emergency Fleet Corporation has authorized the construction of a 50-ft. (15.2-m.) section of a 9600-ton standard ship at the yards of the Federal Shipbuilding Company, Newark, for demonstration purposes and for the development of methods of applying electric welding to an actual ship structure. The construction of this 50-ft. section will be under the direction of Arthur Mason of the Fleet Corporation, who has done much to stimulate interest in the subject of electric welding and also to develop methods of its application to shipbuilding. This ship section is to be sealed up at the ends, filled with water, and tested by hydrostatic pres-

sure. The foundation for this structure is already complete, and work will be pushed as rapidly as possible. Both spot and arc welding are to be employed.

Several meetings of shipbuilders in the various districts have been held, with the result that much enthusiasm has been aroused, and shipbuilders have indicated that they are willing to push the work just as far as the classification societies, the Fleet Corporation and the Navy Department will allow.

Large stationary and portable spot welders are being designed for this work, and various arc-welding systems are being studied. A considerable installation will be made in the Hog Island yard at Philadelphia, under the general direction of Admiral Bowles of the Fleet Corporation.

The committee as now organized consists of numerous active sub-committees, many of the members of which are devoting practically all of their time to the work.

The committee is responsible to Daniel H. Cox, manager of steel ship construction of the Emergency Fleet Corporation, who is lending every possible assistance to its work.

H. M. Hobart, chairman of the original sub-committee, spent several months in England investigating the electric welding work done by the British Admiralty, and brought back some valuable data. As a result of this visit, Capt. James Caldwell, R. E., representing the British Admiralty, is spending a couple of months here to help the committee in this work and to tell of the work along similar lines which has been carried out in England. In company with members of the committee he has visited many of our shipyards and has aided greatly in arousing interest in this movement. One important phase of the present work of the committee is the training of arc welders, of whom thousands will probably be required in the comparatively near future. This work is under the direction of E. E. McNary, Emergency Fleet Corporation, Sixteenth and Walnut Streets, Philadelphia, Pa.

The committee is collecting available information and data as to apparatus, tests and applications. This information, together with much already in hand, will be classified and sent out to all steel shipbuilders and to others interested.

20,000-Ton Coal Storage in Iowa

At Prairie Creek, several miles from Cedar Rapids and directly alongside its interurban railroad right-of-way, the Iowa Railway & Light Company has constructed a 20,000-ton submerged coal storage. The site is within easy hauling distance of the company's main 16,000-kw. steam power station at Cedar Rapids.

Secretary Lane Pleads for Water-Power Law

He Tells Congressional Committee that All of the Country's Resources Must Be Developed in a Large and Generous Way, but that No Development Can Be Had Under Existing Laws

HEARINGS on the "administration" water-power bill were continued before the joint power committee of the House of Representatives in Washington on Wednesday of this week. Practically all of the morning session was given over to Secretary Franklin K. Lane of the Department of the Interior, who appeared in support of the measure.

As father of the commission idea incorporated in the bill and as spokesman for the administration, Secretary Lane made out a very strong case. He insisted that nothing vital or fundamental should be surrendered by the government and that having safeguarded these matters through a fifty-year lease with provisions for recapture, inducements should be made to attract private capital so that the water powers will be put to use as speedily as possible.

After pointing out that the bill now before the committee has a long history and reciting some of the attempts to bring about water-power legislation during the past five years in which he and others have been concerned, Secretary Lane said that the matter of developing one bill in Congress was taken up and that there was strong opposition in some quarters against any kind of leasing system.

"Perhaps a very considerable portion of the time I have devoted to this matter," Secretary Lane said, "has been spent in attempting to convert members of the House and Senate who had notions in opposition that the leasing system was the only practicable one."

REVOCABLE PERMITS NOT ATTRACTIVE TO CAPITAL

The Secretary pointed out that there is still on the books a statute under which revocable permits are granted, but that the men who have money to invest in water-power propositions are not willing to allow any official to say when the investment they have made shall be thrown to the winds. The result, he said, has been that "we have stood for five years of which I know almost entirely without development of one of our great resources."

Secretary Lane continued: "Now, it is not merely the West that is concerned in this. It is the East just as well. Right now I can call your attention to one particular matter that shows how intimately East and West are tied up on such a proposition. You know John D. Ryan of the Montana Power Company. He has private rights, or his company owns certain dam sites and rights along rivers in Montana. I sent out a general request some time ago that the Eastern minerals which had not been heretofore developed in very great quantities, such as manganese and chrome, should now be developed for the purpose of saving ships.

"We get manganese, as you know, from Brazil. It takes a very large tonnage. We import some 800,000 tons a year. We get chrome from Africa and New Caledonia. We get nitrates from Chile, and for all those things a very large number of ships are at present required. We are short, the Allies are short, for

the carrying of nitrates to the other side and to the side—short for carrying pyrites from Spain to the side—short for carrying manganese from Brazil—short for carrying food to our own boys on the other side and munitions and food for the Allies; and no matter what comes out of this German drive now going on over there, there is an obligation upon us, and the pressure of necessity that we should supply those people on the other side.

"For that we must have ships. Now, Mr. Ryan came to me and said he had a plant in Montana which will develop 150,000 hp. That horsepower can be used in a process by which the low-grade manganese ores we take out of the Butte mines can be reduced, and by their reduction they can be made commercially available to the plant in Pittsburgh.

"So that a water power 2000 miles away in Montana makes possible the development and the support of industries in Pittsburgh and relieves ships that come all the way from South Africa."

INCENTIVE TO DEVELOPMENT

Secretary Lane then again went into the history of the various bills which have been before Congress and said that the executive branches of the government in the present bill, had united upon a measure under which "leases could be made that would govern the navigable waters and the unnavigable waters and control as to public lands and as to forests." He told the committee he felt sure its members would find the House and the Senate united in support of a measure such as that under consideration, which does the following:

"Gives a lease for a definite term of years, not to exceed fifty; gives an opportunity for the government to take over the property at the end of that period; gives an opportunity if the government does not want to take over the property at the end of that time for the lessee to take over the property, and I should say that reasonable terms to him would be that he should have that property if the government does not wish to use it and that he should have that property upon terms that would be more favorable to him than those that others might offer, but that he should have a preference. Into the hands of the men capable of developing them should be given sufficient to make a wise and large investment and development; we cannot save things for men who have no capital or men who go about things with a spade where a steam shovel is needed."

GOVERNMENT OWNERSHIP NOT SOUGHT YET

Secretary Lane spoke of the right of the community, of the nation, pointing out that the right of the people of the United States is superior to any right "that you or I might have to speculate upon those things that are primary resources," and adding that he believes as to lands, and as to minerals, and as to water

owers, that no man is entitled to anything unless he es it.

"If we had money enough," he continued, "if this ere not a time of war, if we could think in the terms money that we are now thinking of, or if four or ve years ago Congress had been willing to expend undreds of millions of dollars in the development of ater power as it is forced now to spend billions of ollars for war, it would be a wise thing to put a large art of the public revenues into such projects where ey are found to be needed.

"I have no doubt in my own mind that such schemes water-power schemes are perfectly practicable from government standpoint, no matter what your sympathies may be respecting government ownership, as a ale, of large utilities. A thing that is as well stand- ized as a water-power scheme can be operated succ- ssfully by the government. But I do not take it that is is exactly a practicable proposition at this time, or probably will it be for many years to come, and it necessary that there should be real development, and at soon."

Mr. Lane proceeded to elaborate his point of view in gard to the impracticability of devoting government unds at this time to the building of water-power ants by discussing the immense demands being made on the treasury now and in prospect.

WAR REQUIRES ALL OUR RESOURCES

"The news now coming from the other side of the ater," Secretary Lane said, "is disheartening, dis- uraging, but it leads me to believe that all the con- sion we can come to is that we are in this thing for longer time than we thought. Not," he went on, "that there is to be any cessation of effort on our art, but there is to be renewed effort, a stronger fight id a longer fight. And if we are to have a long fight, nd if we are to get into this thing with our full rength, if a larger portion of the burden of beating on Hindenburg and the other Germans is to fall upon s, then, surely, it becomes necessary that we should ot delay longer in the development of every resource at we can."

Secretary Lane spoke at this point again of the trate situation, pointing out that it is not one that an be looked upon with equanimity and remarking at "the more nitrates we have the more food we can et," and that "there is a large portion of the acre- ge of this country that is now coming to need fertil- ers of one kind or another." Mr. Lane then told of n offer he had had from a company in Washington ve years ago for the development of a water-power roposition.

"That proposition," Mr. Lane continued, "could have een financed successfully at that time if we had had uch a bill as the one which is now before you. Then ey wished to go into the business of developing ni- rates. The power is still there and is still unused."

GOVERNMENT MONEY NOT FOR PRIVATE ENTERPRISES

He said there are propositions of this kind all over e country, and that there is a supreme obligation pon all of the people of the country at this time, as ell as its officials, to think more seriously of such ings, and that "we will get no development under the resent law."

Answering questions by Chairman Sims, presiding

at the meeting of the committee, Secretary Lane, be- fore entering upon a general discussion of his remarks, participated in by almost all members of the committee, said that if there is a determination by Congress that there shall be water power development, for instance, along the Columbia River, or the Snake River, or the Colorado River, for the production of low-grade manga- nese, or for the development of nitrates, either for gunpowder or for fertilizer, and such works could not be financed, then "it is the duty of the federal govern- ment at this time to help out the proposition and put it on its feet." He added:

"I am not sympathetic generally with the idea of having the government lend money to private enter- prises because it is a hard thing to get it back.

DEVELOPER SHOULD HAVE CONSIDERATION

"But," Mr. Lane went on, "I am very much in sympa- thy with the government doing what it pleases with its own money, provided it knows where it is going, and what it wants, and how that money can be prop- erly handled, and I am not afraid at all of the govern- ment undertaking the development of water-power propositions, because we have had some experience with them in the Reclamation Service. The Salt River propo- sition which I have turned over to the water users is practically paying its own way now out of the power developed out of the Roosevelt dam. That was a ven- ture at the time. All of these propositions are gam- bles. That is one reason why a man who puts his money into a water-power project has got to have very real consideration. He is a developer, and every man who is a pioneer of any kind takes the risk, and for his risk he ought to be compensated."

Mr. Lane was asked some questions as to whether it will be possible for water-power plants to be built in time to be of service before the war is over. Very close attention was paid to the answer of the Cabinet of- ficer on this point because men in public life in Wash- ington have not recently been hazarding guesses as to the length of time which the struggle will continue. He said:

"I have no expectation that this war will be over be- fore water-power projects such as many that we know of can be developed. I think you have got to look at that thing with a long range."

OPPORTUNITIES ON NAVIGABLE STREAMS

M. O. Leighton, consulting engineer, Washington, D. C., and for many years with the United States Geo- logical Survey, who spoke on Wednesday afternoon, said that at least 10,200,000 hp. could be developed on 4325 miles of navigable streams at an expense of \$800,000,000 for canalization. He estimated that as much as 2,000,000 hp. would be developed or in process of development five years after the passage of a favor- able water-power measure, like the administration bill as amended during the hearings.

As showing the effect of unfavorable legislation on water-power development Mr. Leighton cited the gen- eral dam act of 1910 under which fifty-five grants were made, out of which only two could be financed.

The public hearings on the bill were suspended for the time being, it being decided to set aside another day to be announced later, at which time some Con- gressmen and the two other members of the Cabinet who will form part of the commission will be heard.

NATION'S BUSINESS MEN FOR WATER-POWER LEGISLATION

Five Hundred Thousand Business Executives Vote
Through United States Chamber of Commerce
for Action by Congress

By sweeping majorities 500,000 business executives, who compose the membership of the United States Chamber of Commerce, have adopted resolutions calling on Congress to make provision for water-power development.

The vote was taken through the more than 1000 commercial organizations throughout the country which compose the national chamber. Forty-five states, Alaska and Hawaii participated in the balloting, representing a wide range of industrial interests and opinions and reliably indicating to Congress how the business men of the nation look on the water-power situation.

The balloting was based on a series of recommendations contained in the report of the committee on water-power development of the Chamber of Commerce. These recommendations were:

That federal legislation encouraging the development of water power should at once be enacted. Adopted by the almost unanimous vote of 1324 to 6.

The authority to grant permits should be vested in an administrative department. Carried by a vote of 1253 to 17.

That the permit period should be at least fifty years, any shorter period being at the applicant's option. In favor 1216, opposed 42.

That tolls should attach only to use of public lands or benefits derived from head-water improvements. Adopted by vote of 1191½ to 40½.

That permittees should be entitled to acquire the right to use public lands forming only a small and incidental part of the development. Carried by a vote of 1210 to 25.

That recapture should be exercised only upon payment of fair and just compensation. In favor 1234, opposed 25.

That if recapture is not exercised the investment of the permittee should be adequately protected. Adopted by vote 1226 to 26.

That rates and service should be regulated by state commissions where the service is intrastate, with federal regulation only where several states are directly concerned and do not agree or there is no state commission. Carried by a vote of 1177 to 57.

That if any jurisdiction to regulate the issuance of securities it should be solely by the state. In favor 1114, opposed 117.

That no preference should be granted as between applicants amounting to a subsidy from the government, creating unequal competition. Adopted by a vote of 1191 to 38.

The committee which drew up the report and presented the resolutions was composed as follows:

L. S. Gillette, chairman, engineer and manufacturer, Minneapolis; Harry A. Black, wholesale merchant, Galveston; Rome G. Brown, lawyer, Minneapolis; Henry S. Drinker, president Lehigh University; Frank P. Glass, editor-in-chief *Birmingham News*; E. K. Hall, lawyer, New York City; Horace C. Henry, retired railway contractor, Seattle; Henry L. McCune, lawyer, Kansas City; Samuel V. Stewart, lawyer and banker, Virginia City, Mont., and Governor of Montana; George F. Swain, civil engineer, Boston, and C. F. Weed, lawyer and banker, Boston.

While the committee report is in itself favorable to positive legislation to enlarge water-power development, every ballot sent out was accompanied by an argument in the negative which clearly and positively set forth objections to the recommendations so that those

voting had at hand data on which to base their judgment for or against.

The report begins by pointing out that it is estimated that the undeveloped water power of the country exceeds the total steam power now in service. The federal government controls much of the water-power resources of the country. The report adds:

One of the first things to be clearly perceived is that water-power developments are not exceedingly profitable undertakings earnestly sought by capital as a means of securing large returns on a small investment, but that, on the contrary, steam power is the superior of water power in almost all respects.

The initial cost of a steam plant is in general but one-half to one-fifth that of a water-power plant of equal capacity. Moreover, a steam plant can be more easily enlarged from time to time and the initial development of a water-power plant must be a larger proportion of the ultimate development than that of a steam plant. The investor in a water-power plant is therefore burdened from the very start with a heavy fixed charge.

Water powers will not be developed unless the conditions are made comparatively favorable. Present demand for the development of such power comes, not from capitalists, but from communities which, on account of the high price and scarcity of fuel, are desirous in their own interest of inducing capital to make such developments.

EFFECT OF WAR CONDITIONS ON THE PUBLIC UTILITIES

Committee Representing the N. E. L. A. and Other
Utilities Takes Positive Steps to Present the
Facts Throughout the Country

The National Committee on Public Utility Conditions composed of Philip H. Gadsden, E. K. Hall and H. H. Crowell, has issued a statement dealing with the serious war problems affecting public utilities. The committee represents the National Electric Light Association, the American Electric Railway Association, the American Gas Institute and the National Commercial Gas Association.

The committee also announces the personnel of regional and state committees, the regional committees having the function of appointing state committees in their districts. The committees announced are:

REGIONAL COMMITTEES.

Maine, New Hampshire, Vermont, Massachusetts and Rhode Island.—H. G. Bradlee,* Stone & Webster, Boston; C. L. Edgar, Edison Electric Illuminating Company, Boston.

New York, Pennsylvania, Connecticut, New Jersey and Maryland.—J. K. Choate,* J. G. White Management Corporation, New York City; T. N. McCarter, Public Service Corporation of New Jersey, Newark; C. M. Cohn, Consolidated Gas, Electric Light & Power Company, Baltimore.

Ohio, Michigan, Indiana and Illinois.—B. I. Budd, South Side Elevated Railroad, Chicago; H. H. Crowell,* Michigan Railway, Grand Rapids; F. W. Coen, Lake Shore Electric Railway, Sandusky.

Wisconsin, Minnesota, South Dakota, Iowa, Nebraska, Kansas and Missouri.—P. J. Kealy, Kansas City Railway; William Chamberlain, Brown, Chamberlain & Hanselick, Cedar Rapids; James D. Mortimer,* North American Company, New York City.

Utah, Colorado, Idaho, Wyoming, Montana, Washington and Oregon.—F. T. Griffith, Portland Railway, Light & Power Company, Portland; M. H. Aylesworth,* Utah Power & Light Company, Salt Lake City; G. W. Talbot, Pacific Power & Light Company, Portland.

*Asked to assume responsibility of organizing committee.

California and Nevada.—J. A. Britton,* Pacific Gas & Electric Company, San Francisco; Paul Shoup, Pacific Electric Railway, Los Angeles.

Virginia.—George J. Seay,* Government Federal Reserve Bank, Fifth District, Richmond; B. B. Ferguson, Portsmouth Gas Company; J. W. Hancock, Lynchburg Traction Light Company, Lynchburg; T. S. Wheelwright, Virginia Railway & Power Company, Richmond.

Georgia.—R. C. Congdon, Atlanta Gas Light Company; J. S. Bleeker, Columbus Electric Company; P. S. Arkwright,* Georgia Railway & Power Company, Atlanta.

STATE COMMITTEES.

Alabama.—J. S. Pevear, Birmingham Railway, Light & Power Company.

Arizona.—R. G. Arthur, Douglas Traction & Light Company.

Arkansas.—C. J. Griffith, Little Rock Railway & Light Company.

Delaware.—T. W. Wilson, Wilmington & Philadelphia Traction Company.

Florida.—C. I. Day, Southern Utilities Company, Jacksonville.

Hawaii.—L. T. Peck, Honolulu Rapid Transit Company.

Kentucky.—Donald McDonald, Louisville Gas & Electric Company.

Louisiana.—D. D. Curran, New Orleans Railway & Light Company.

Mississippi.—H. E. Brandli, Meridian Light & Railway Company.

New Mexico.—W. S. Townsend, Las Vegas Transit Company.

North Carolina.—R. L. Lindsey, Durham Traction Company.

North Dakota.—R. B. Griffith, Grand Forks Street Railway.

Oklahoma.—J. W. Shartel, Oklahoma Railway.

Philippine Islands.—C. N. Duffy, Manila Electric Railway & Light Corporation.

Porto Rico.—O. M. Sewall, Porto Rico Railway, Light & Power Company, San Juan.

South Carolina.—William Elliott, Columbia Railway, Gas & Electric Company.

Tennessee.—T. H. Tutwiler, Memphis Street Railway.

Texas.—L. C. Bradley, Stone & Webster Management Corporation, Houston.

Washington, D. C.—Howard Reeside, Washington Gas & Light Company.

West Virginia.—J. O. Watson, Monongahela Valley Traction Company, Fairmont.

In its announcement the National Committee on Public Utility Conditions calls attention to the recent public expressions by President Wilson, Secretary of the Treasury McAdoo and Comptroller of the Currency Williams in which these important officials made clear their understanding of the serious needs of the properties. The committee adds:

The officers of the national associations believe the reasons that actuated those government officials in sounding public warning of the necessity for liberal and sympathetic treatment of utilities should be brought to the attention of regulatory commissions and local authorities by the national associations interested, not from the standpoint of particular corporation or utility and not affecting the interests of any one company or group of companies, but solely with regard to the broader national interest involved in the relation of the utilities to the general war program and the whole financial structure. Something more than the preservation of these utilities themselves is at stake.

While new construction and extensions will during the period of the war be held down to necessary requirements, it is absolutely impossible to refuse arbitrarily to make additions or extensions. The direct war program or the general welfare of the public will require in most sections of the country some additional service. This, of course, requires funding of extensions to plants which can

be asked to assume responsibility of organizing committee.

only be consummated by the rehabilitation and preservation of the credit of the utilities. The rapidly rising line of increasing operating costs has in some instances already crossed the horizontal line of inflexible rates—rates that were fixed on a pre-war basis and that are totally inadequate to meet existing conditions.

The securities of public utilities have long been a favorite form of investment for both small and large investors, savings banks, insurance companies and trustees, and are to be found as collateral for loans in every national and state bank. Their depreciation accordingly threatens the whole financial structure. If relief cannot speedily be had and the companies are forced generally to adopt the practice of suspension of dividends, the nation's ability to subscribe for Liberty bonds, and one of the government's chief sources of supply for income taxes, will be seriously diminished.

The conclusion reached by the officials of the government in Washington, from their study of the situation, was that the really fundamental solution of the problem lay in a speedy increase of rates to absorb the increased costs of doing business brought about by war conditions. It is equally clear that they were satisfied that the ordinary procedure for an increase of rates was utterly inadequate to meet the emergency.

It is the belief of the national associations that if the general public utility situation can be presented to the state commissions and municipal authorities along the same general lines on which it was presented to the authorities in Washington they must inevitably come to the same conclusion. Accordingly, the national associations are undertaking to have the general public utility situation brought to the attention of the state commissions and municipal authorities in conference entirely dissociated from any individual rate case, in the hope that the matter of increased rates may be approached from the broad point of view of the vital general public and community interest and the interest of the nation itself, rather than solely from the viewpoint of a controversy between a local utility and its patrons.

Apparently several of the commissions do not realize that the whole principle of regulation is now receiving its supreme test. If it is found to be too inelastic to respond promptly to abnormal conditions, it will have failed to justify its existence. It is vastly more important that the regulatory system should demonstrate its ability to preserve the efficiency and comprehensiveness of the service than it is to demonstrate that it is able to prevent here and there an occasional exorbitant rate, all of which have long ago been corrected.

Every one will agree that no public utility ought to make any additional profit by reason of the war, but this is an entirely different proposition from the suggestion that their profits should be cut during the war. Utility profits at all times are limited to a reasonable return on the investment. Anything less than that becomes permanent loss, for it can never be recouped from profits always limited to a reasonable return. The result is sure to be impairment of utility credit and reduction in the efficiency of its service.

If a utility's "assuming its share of the burdens of the war" means that officers and employees of public utilities must furnish more service with fewer facilities and equipment to work with than under normal conditions; that they must find a way to continue these services, notwithstanding increasing costs of materials and labor; that they must work harder to overcome extraordinary obstacles and handicaps in order to accomplish more than ever before, then of course the public utilities should bear their share of the burdens of the war, and they are doing it now and will continue to do it gladly. But if it is intended to suggest that the utilities should furnish these services at less than the cost of production and that these services should in part be rendered gratuitously, this is asking them to carry more than their fair share, it is neither just nor in the public interest, for the result must be impairment of credit, shrinkage of value and securities, reduction in dividends and a consequent reaction upon the many thousands of investors holding these securities which will diminish their capacity to subscribe for government loans and ultimately threaten the foundations of the general credit structure of the entire country.

EXTENSIVE DEVELOPMENT IS URGED IN CALIFORNIA

Railroad Commission, Studying Increased Demands for Power and Necessity of Fuel Conservation, Recommends \$20,000,000 Expenditures

Recommending extensive hydroelectric developments in southern California, at an expenditure of perhaps \$20,000,000 within the next two years, to meet increasing demands for power and light and for the conservation of fuel, the California Railroad Commission issued on March 19 a decision in its investigation of the construction and operation of electric utilities during the emergency created by the war.

The commission recommends that the Southern California Edison Company take immediate steps for carrying out of a comprehensive plan for financing approximately \$15,000,000 for building power plants, that the Southern Sierras Power Company construct its Rush Creek-Bishop line, and the San Joaquin Light & Power Corporation insure the building of additional plants for the increases of facilities, or, by purchase agreement, the maintenance of an adequate power supply for agricultural and industrial needs.

The commission investigation was State-wide, but the present decision deals only with the territory south of Merced, the northern part of the State to be considered later. The decision says that, though considerable economy of oil would result from more complete interconnection and co-operation of hydroelectric plants, yet the war emergency demands that the corporations take immediate steps to build additional power plants to meet the constantly growing need for power made by the normal increase of manufacturing and agriculture and the special needs of war industries, which are rapidly multiplying in California.

The southern part of the State which is considered comprises that portion of the San Joaquin valley south of Merced and served by the San Joaquin Light & Power Corporation and the Mount Whitney Power & Electric Company, and southern California, which is served by the Southern California Edison Company, the Southern Sierras Power Company, the San Diego Consolidated Gas & Electric Company, the Los Angeles Gas & Electric Corporation and the city of Los Angeles.

The power produced by these companies in 1915 was approximately 930,000,000 kw.-hr., in 1916 1,010,000,000 kw.-hr., and in 1917 1,146,000,000 kw.-hr. Of this latter amount, 911,000,000 kw.-hr. was produced by hydroelectric plants, and the remainder by steam, requiring a total oil and natural-gas consumption amounting to an oil equivalent of 1,316,000 barrels of oil. It is estimated that the growth in business due to the normal developments and the special war industries will approximate 140,000,000 kw.-hr. a year and a requirement of plant capacity of about 25,000 kw.-hr., and that in order to keep down the oil consumption of electric utilities to that existing in 1917 will require that amount of development each year.

The report shows that considerable economy will result from the interconnections now existing and those contemplated by the companies, but that even with this saving it will be necessary to increase the hydroelectric facilities at least 20,000 kw. of useful capacity a year and increase the energy output approximately 140,000,000 kw.-hr. under ordinary rainfall conditions.

Consideration was given to existing and proposed developments of the city of Los Angeles in connection with the aqueduct, where it appears that at a cost of between \$2,500,000 and \$3,000,000 the city would produce an additional peak capacity of 36,000 kw.-hr. and an output of at least 115,000,000 kw.-hr. a year, resulting a reduction of oil consumption of 600,000 barrels a year.

The commission states that the development by the city could be largely completed within twelve months if priority orders were obtained for equipment, but that difficulties exist which apparently make it impossible at this time to count on the development of the plan. These difficulties arose from the fact that the city of Los Angeles contends that it cannot utilize bonds already authorized for the development of hydroelectric plants, but that this money must be used for the construction of distribution systems. The city believes that if a satisfactory agreement could be entered into with the Los Angeles Gas & Electric Corporation whereby that company would lease to the city its entire system, such agreement to contain an option for purchase, the money could be used for hydroelectric plants.

The Los Angeles Gas & Electric Corporation, however, declined to consider the plan, which it contends constitutes a complete surrender of the possession of its distribution system to a competitor, and also that its true provisions make such a plan a legal impossibility.

ACTIVITIES OF THE NATIONAL COMMITTEE

Work of the National Committee on Gas and Electric Service for the Utilities in Connection with the War

The National Committee on Gas and Electric Service, of which J. W. Lieb is chairman, has issued a report on its recent activities, saying in part:

Replies have been received by the committee from various public utilities requested to furnish information showing the output of either electric energy or gas to be used by manufacturers turning out war material. The data have been turned over to Dr. Garfield. Some of the reports show an amazingly high percentage of output furnished for this purpose. The committee is working with the conservation department of the Fuel Administration Bureau on several plans to conserve the consumption of coal.

The War Department has recently asked the committee to obtain information as to the possibility of taking over 200,000 kw. in turbine units which have been ordered by central stations from the large electrical manufacturing companies. This does not necessarily mean that the turbines will be commandeered, but a survey of these conditions has been thought necessary by the department, and the committee has been used as the avenue for procuring this information.

This machinery is to be put to use in connection with the various nitrogen fixation plants, power and explosive plants, chemical and gas manufacturing plants which it is proposed to establish throughout the United States. In perfecting arrangements for the construction of these various government plants it has been found that through tying-in of some of the near-by electric systems a sufficient amount of electrical energy can be secured to make it unnecessary to put up isolated electric plants. This applies however only to the smaller operations. Several of the large operations it is estimated will require approximately 90,000 kw. or 100,000 kw. of electrical energy, and as it is proposed by the government to erect several such plants it can be seen that the necessity for turbine equipment is rather alarming.

Current News and Notes

Timely items on electrical happenings throughout the world, together with brief notes of general interest.

J. Robert Crouse Addresses Lamp Works Employees.—J. Robert Crouse, in charge of the thrift stamp campaign in Cleveland and Cuyahoga County, Ohio, addressed 1000 employees of the National Lamp Works of the General Electric Company on March 15.

Government Transmission Line.—Application has been made to the Northwestern Ohio Railway & Power Company by the United States government for figures on the cost of erecting a transmission line from a point about 70 miles south of Camp Perry. It is understood that the government is to furnish all material and attachments for this line and also to pay the entire cost of installation, the line remaining government property when completed.

Cannot Install Additional Lights in Toledo.—Henry L. Doherty has informed the Toledo City Council that, owing to requests from the government that no additional demands be made for electric equipment, the Toledo Railways Light Company will be unable to install the 100 arc lamps the city has requested. He also denied that the city had been overcharged for the service rendered in street lighting, as indicated by a report made by Toledo University teachers.

Electrical Engineer Wanted at Albany.—The Civil Service Commission of New York State, Albany, announces an examination on April 27 for a position as electrical engineer in the office of the state architect, salary \$1,800, as follows: "The duties of the position include the preparation of plans and specifications for the installation of electric wiring and fixtures in both new and old buildings and for the installation of central electric generating plants and feeder systems. Candidates must have had five years' satisfactory experience in electrical work, two years of which must have been directly in the drafting of electrical plans."

Instruction for Soldiers in Kansas.—L. A. Potter, dean of the division of mechanical engineering of the Kansas State Agricultural College, who has been lecturing to soldiers at Camp Funston, near Manhattan, Kan., has invited the men to take short courses at the college in the lines of work which they are studying at the camp. The present plan is for about 300 men to be assigned for two or three weeks to attendance at the college. These men will be distributed through the departments in which they are interested and will have work and instruction every day, their classes to be arranged so as not to interfere with regular college classes. Besides the instruction, the college plans recreation for the men.

Automatic Hydroelectric Station Operating Satisfactorily.—The 1500-kw. automatic hydroelectric generating station of the Iowa Railway Light Company at Cedar Rapids, Iowa, which was described in the ELECTRICAL WORLD of Dec. 1, 1917, has just completed six months of entirely satisfactory operation. In that time it has delivered about 2,500,000 kw.-hr. It is the opinion of John M. Drabelle, electrical engineer of the Iowa Railway & Light Company, that the station in this six months' period has seen exceptionally severe service and has met every emergency in an entirely satisfactory way. No changes in the station have been made since it was described.

Heating Service Curtailed in Springfield, Ill.—A. D. Mackie, general manager of the Springfield (Ill.) Gas & Electric Company, in announcing that heating service to several customers now on its mains will be discontinued with the beginning of the next heating season, says in part: "If all our electrical service customers went over to the municipal plant, it would then be necessary for us to abandon entirely our heating service. By the same rule, if one-half of our electric service customers went over to the municipal plant, it would cut down our available heating service by one-half and compel us to discontinue heating service to one-half our heating customers. In lesser degree this is the situation that now confronts us, one in which we believe our customers readily will see the justice of the proposition that those that aid in producing heating service should be able to retain that service, rather than those that do not aid in producing it."

Montana Power for Ferromanganese Manufacture.—The Anaconda Copper Company of Montana is entering into the ferromanganese business. John D. Ryan, in a letter to Secretary of the Interior Lane, says that ferromanganese is to be manufactured through the utilization of low-grade manganese ores in the Butte mines that have never been worked before. His letter reads in part: "In ordinary times these ores would have no value, and to transport them in the raw state and manufacture the ferromanganese in the East, even under war conditions, is impracticable on account of the cost, shortage and difficulties of transportation. To manufacture these low-grade ores into an 80 per cent ferromanganese product within a very short distance of where they are produced by the use of hydroelectric power that is available without taking it from any other use seems to me in itself a matter of much interest in these times, but the greatest accomplishment in doing this will be the release of the equivalent of ten ships of 5000 tons each now used in bringing manganese from Brazil. The power is available from the Holter development, completed within a month by the Montana Power Company as a reserve and in advance of its market requirements. This plant is capable of furnishing 40,000 kw. twenty-four hours daily the year round."

Recent Court Decisions

Findings of higher courts in legal cases involving electric light, power and other public utility companies.

Flooding State Lands.—The code authorizing the State land commissioners to grant right of flooding state lands for power purposes, etc., precludes condemning the right to overflow State lands by one whose application to the commissioners had been rejected and the right granted to another, especially where both parties are seeking to make the same use of the land, the Supreme Court of Washington held in *Mason County Power Company versus Superior Court for Mason County* (169 P. 994).

Powers of Commission.—The Public Service Commission act does not deny to public service corporations the common-law right to make regulations nor vest such power in the Public Service Commission in the first instance, but said commission may, on finding such regulations unjust, unreasonable, insufficient or unjustly discriminatory, annul them and substitute others for them, according to the Supreme Court of Appeals of West Virginia (94 S.E. 545). If a regulation prescribed by such corporation is just, reasonable and fair, even though it is discriminatory, the discrimination it makes resting upon a classification of subjects based upon substantial differences in situation and circumstances, this power to annul does not vest in the commission. In so far as the contracts of public service corporations conflict with public duties imposed upon them by law, they are not within the protection of the constitutional provision inhibiting impairment of the obligations of contracts.

Shutting Off Service.—In a consumer's action against a gas company for wrongfully and without just cause shutting off his supply of gas, the burden was on plaintiff to offer evidence legally sufficient to show that he was not indebted to the gas company for gas supplied to the premises at the time the supply was shut off, for unless such evidence was offered there was a failure of proof to support the allegations of the declaration that the supply was wrongfully and without just cause shut off, the Court of Appeals of Maryland held (102 A. 465). Where a consumer of gas used approximately \$23 worth during a month, but his meter contained only about \$11 in quarters in payment, so that he was indebted to the gas company in about \$12 for gas consumed on his premises, and the meter was removed by the company without unnecessary force or disturbance after his failure to pay by a fixed date on notice, the company was not liable for wrongfully shutting off the consumer's supply of gas and was acting within its legal rights in removing the meter.

Associations and Societies

A complete Directory of Electrical Associations is printed in the first issue of each month on the next-to-last text page.

Synchronous Club of Los Angeles.—S. J. Keese presented an illustrated lecture on "Light and Color Waves" before the Synchronous Club of Los Angeles on March 22.

Electric Club-Jovian League of Chicago.—"Wireless Communication with Airplanes" was the title of an interesting address given before the Electric Club-Jovian League of Chicago on March 21 by Prof. F. A. Rogers of Lewis Institute, Chicago.

San Francisco Electrical Development League.—Prof. B. M. Woods, president of the Academic Board, School of Military Aeronautics, University of California, spoke at a luncheon on March 13 before the San Francisco Electrical Development League on "How Americans Are Trained to Fly."

Cleveland Electrical League.—A spectacular review entitled "Wake Up, America," was produced by John H. Patterson, president of the National Cash Register Company, for the Cleveland Electrical League on March 14. On March 21 A. C. Gilbert, of the Cleveland Trust Company, addressed the Electrical League on "German Influences in South America—One Bloody Battle the Kaiser Lost."

Spring Meeting of American Electrochemical Society.—During the week of April 28 the American Electrochemical Society will hold its spring meeting by making a tour through Tennessee and Alabama and stopping at important electrochemical centers and water-power developments in these States. Arrangements will be made for visiting Johnson City, Kingsport, Knoxville, Sheffield, Muscle Shoals, Chattanooga, Anniston and Birmingham. A special train will be provided.

Ohio Electric Light Association New-Business Men's Section.—On March 20 the New-Business Men's Section of the O. E. L. A. held a lively meeting at Columbus, in which new-business getting and money raising for public utilities were discussed. In an address on "Contracts and Their Legality" A. Eastman said that the law under which the interstate commission acted and the Ohio law were practically the same in reference to contracts, and that all contracts must contain the published rate and be filed with the interstate commissions. A paper presented on "Domestic Refrigeration" brought out the fact that a special rate should be created on this kind of energy-consuming device, as the load obtained by it was very desirable. The next meeting of the New-Business Men's Section will be in Cleveland on May 6.

Los Angeles Jovian Electric League.—At the March 13 luncheon of the league Seward A. Simons spoke on "The Bright Side of the War." P. C. Ensley, of the Graham-Reynolds Electric Company, acted as chairman of the day.

Philadelphia Section, A. S. M. E.—On March 23 Major W. P. Barba and Major A. F. Cushman discussed subjects relating to the corrosion of boiler tubes before the Philadelphia Section of the American Society of Mechanical Engineers.

Wisconsin Electrical Association.—The annual convention of the Wisconsin Electrical Association was held on March 27-28 at the Hotel Pfister, Milwaukee, in joint session with the Wisconsin Gas Association. Some of the important papers presented were as follows: "The Utilities and the War," by M. C. Ewing, secretary-treasurer of the Wisconsin Valley Electric Company, Wausau; "Metal Electrode Welding," by Dean Treat, manager Wisconsin Railway, Light & Power Company, La Crosse; "Increasing the Efficiency of Hydroelectric Plants," by Daniel W. Mead, of Mead & Seastone, consulting engineers of Madison, and "Three-Phase Four-Wire Distribution," by George E. Wagner, superintendent of plant, Madison Gas & Electric Company. The feature of the meeting was an address by W. N. Fitzgerald, State Fuel Administrator for Wisconsin.

A. I. E. E. Section Meetings.—John B. Taylor, consulting engineer, Schenectady, N. Y., talked on "Vibrations" before the Boston Section on March 19. E. A. West, chief engineer of the Denver Tramway Company, gave a talk on "Power House Efficiency" before the Denver Section meeting on March 16. W. T. O'Connell spoke on "Design of Outdoor Substations" before the Panama Section recently. The subject of indoor versus outdoor substation in the Canal Zone was discussed by the members. A. O. Austin, chief engineer of the Ohio Insulator Company, Barberton, Ohio, gave an interesting talk on "Improvements in Design, Manufacture and Use of Porcelain Insulators" before the Rochester Section March 22. The lecture was well illustrated by numerous slides showing insulators. "The Economic Basis of Industrial Activity" was discussed by D. B. Rushmore, engineer of the power and mining department of the General Electric Company, before the Schenectady Section on March 20. "A Little Light on Lighting" was a subject discussed by J. J. Curran, Curran Sign Company; V. H. Griesser, electrical engineer, W. W. P. Company, and T. E. Holsey, illuminating engineer, W. W. P. Company, before the Spokane Section meeting recently. H. M. Leathers, of the Cutler-Hammer Manufacturing Company, delivered an address before the Toledo Section on "The Measurement of Gas by Electricity" on March 20. The lecture was supplemented by lantern slides showing parts of the apparatus and typical installations.

Commission Rulings

Important decisions of various state bodies involving or affecting electric light and power utilities.

Inefficiency Penalized.—The Illinois Public Utilities Commission decided, in a recent case, that it will not allow as high a rate of return where the business of a utility has been conducted upon an unsystematic basis as it will in a case in which the business has been efficiently managed.

Competing Franchises and Steam Reserve Stations.—The New York Public Service Commission, Second District, holds in a decision affecting the Lockport Light, Heat & Power Company that when a city grants franchises to two different corporations enabling them to compete for the electric light and power business in the community, and the companies are afterward merged or consolidated, the city cannot successfully urge that the owners of the property which was installed for the benefit of the people of the city shall not be allowed to earn a fair return upon the value of all the property employed in the public service. The fact that there may be a duplication of property is due to the situation which was created by the city when it granted two franchises to two separate corporations, and the owners of the property must be allowed a reasonable opportunity to work out of the difficulty. In regard to the necessity of a steam reserve station the decision says: "It is a well-known fact that a concern like the Lockport company cannot always be assured that it will have a never-failing supply of hydroelectric power, even though it does come from the mighty Falls of Niagara. Delays and interruptions are a necessary incident to the business of transmitting electric energy from the source of supply to the point of distribution over long transmission lines; they are in most instances inevitable. When this happens, all the industries dependent upon this power are subject to serious loss and inconvenience, even if the interruption in the service is only of brief duration. There is hardly an electric light and power company of any consequence in the State purchasing hydroelectric energy for distribution which has not some sort of steam reserve to back it up for the purpose of taking care of interruptions as well as to cut down the peak, inasmuch as hydroelectric power is usually sold on the basis of the peak-load demand. It may be that the steam plant will not be called on for weeks at a time to supply electricity because of the failure of the hydroelectric energy, but when it is needed it is there ready for use, and it enables the company to continue to supply its customers and reduce losses which might otherwise result."

Frank W. Hall, recently appointed commercial manager of the Sprague Electric Works of the General Electric Company, dates his connection with the company from the year 1895, when he

F. W. HALL

joined the student engineering course of the Sprague Electric Elevator Company at the Bloomfield factory. During the ensuing five years Mr. Hall was occupied in superintending installation work on Sprague elevators, in special work in the factory engineering department, and later in the traveling engineering inspection of elevators. After the Sprague Elevator Company was merged with the Interior Conduit & Insulation Company and the Sprague Electric Company was formed, Mr. Hall was actively engaged with Robert Lundell in the development at the Bloomfield factory of the split-pole type of direct-current generators. In 1900 Mr. Hall joined the commercial engineering department at the New York office of the Sprague Electric Company, and in 1902 he became district office engineer at Chicago. In 1903 he became assistant to the manager of the hoist sales department in the New York office. In 1905 he left the company to become sales manager for the Hammerschlag Manufacturing Company, returning in 1909 to the Sprague Electric Works as manager of their Philadelphia office. In 1911 he returned to the general office in New York City as manager of the hoist sales department. In 1912 he became apparatus sales department manager, and in 1914 sales manager of all of the products of the Sprague Electric Works. Mr. Hall has taken a large part in electrical manufacturing association work and is at present vice-chairman of the newly formed Electric Hoist Manufacturers' Association, chairman of the outlet-box section and secretary of the fan section of the Associated Manufacturers of Electrical Supplies.

Leon O. Hart has been elected treasurer and director of the Driver-Harris Company at Harrison, N. J. Mr. Hart was born in Hoboken, N. J., in 1885, and received his education at the Stevens Institute of Technology, from which he was graduated in 1907 in me-

Changes in Personnel
and Position—
Biographical Notes

chanical engineering. After graduation he was a cadet engineer with the Public Service Gas Company of New Jersey for about a year, when he became associated with the Driver-Harris Company as electrical engineer, serving in this capacity until March, 1917, when he became assistant treasurer.

Obituary

Edward K. Patton, for the last eighteen years Western manager of the Bryant Electric Company, died of apoplexy at his home in Chicago on March 23. Mr. Patton, who was born in Chilli-

E. K. PATTON

cothe, Ohio, about fifty-eight years ago, first became associated with the electric supply business in 1888, when he was appointed Western manager of the Perkins Electric Switch Manufacturing Company. When, in 1900, that company passed into the control of the Bryant Electric Company, he continued with it in a similar capacity.

John Porterfield Sparrow, who, as reported in these columns last week, died March 18, was born in Portland, Me., March 17, 1860. Mr. Sparrow was an engineer by inheritance and education, his father, John Sparrow, having been well known in the engineering field. His early education was obtained in the public schools of Portland. In 1880 he entered the Portland Company's locomotive and marine engine works as an apprentice, leaving this company in 1888 to work for the Sprague Electric Company. During the next two years he acted as superintendent for the Sprague Electric Company in charge of construction of electric railways in various parts of the country. He went

to New Orleans in 1890 for the New Orleans Electric Company on construction work and two years later joined the construction staff of the Edison General Electric Company and was employed in building lighting and power plants for it and the Canadian General Electric Company until 1895, when he joined the staff of the construction department of the Edison Electric Illuminating Company of New York. In 1898 he became superintendent of construction, having charge of all of the construction which included the new Waterside station, at that time the largest and most important construction of its kind which had been attempted. He became chief engineer of the New York Edison Company in charge of construction and operation in 1906, and held this position at the time of his death. Mr. Sparrow was an active member of the various societies to which he belonged. At the time of his death he was chairman of the committee on standardization of flanges and pipe fittings of the A. M. E. S. and had just finished the completed report on that subject. On Feb. 1 last he was appointed chairman of the advisory board of the power test committee of that society. In the Association of Edison Illuminating Companies he was a member of the committee on steam plants in 1906 and the following years, and he was chairman in 1910, 1912 and 1913. In this work his most valuable contributions were those in connection with coal testing and burning. In the National Electric Light Association he was a member of the committee on prime movers for a number of years and was a frequent contributor to the question box. Shortly after the United States entered the war he made a number of tests for the Naval Consulting Board in connection with smoke abatement on ships as a protection against submarines. Mr. Sparrow's valuable work in the photomicrography of lamp filaments is well known. In later years he turned to metallography in connec-

J. P. SPARROW

tion with the ever present subject of the corrosion of condenser tubes and assisted in the settling of important questions of heat treatment in the manufacture of this material.

TRADE & MARKET CONDITIONS

News of the Trade for the Manufacturer, Wholesaler and Jobber
of Electrical Equipment and Supplies—
Notes on Industrial Activities and Business Methods

ACUTE SHORTAGE OF TIN MAY CAUSE HIGHER PRICES

Manufacturers of Apparatus, Wire and Cable
Express Uneasiness—Cost of the Metal
Advancing

A sharp shortage of tin is not only freely acknowledged now, but it has been in evidence for several months. The supply at the present time is less than ever. Prices have been climbing in harmony with the depleted stocks of the metal in this market. A number of manufacturers were waited upon by the *ELECTRICAL WORLD* to ascertain the true state of affairs in so far as tin and its various alloys and amalgams affected the output and prices on electrical products. At the office of one prominent concern the acute curtailment in tin stocks was frankly admitted and it was stated that the condition of the market is giving rise to a feeling of justifiable uneasiness.

Reserve supplies of tin in the hands of manufacturers of electrical apparatus, wire, cable, dry batteries and other lines are not large. One wire and cable producer said the company had recently bought 5000 lb. of Straits tin at 84 cents, or approximately four times the pre-war normal price. While all metals have appreciated in value, owing to several causes, according to this informant, whose company always carries a large stock in self-protection, tin commenced to jump in price when a number of vessels carrying large shipments were sunk by German commerce raiders early in the war. The *Emden*, which operated in East Indian waters for a long time until sunk by the Australian war cruiser *Sydney*, destroyed a number of cargo carriers, all of which had important invoices of tin aboard.

Prices jumped immediately and have been going up since. The shortage of tin is not occasioned by less of the metal being mined and smelted—to accept the explanation of an important factor in the trade—but the curtailment of tonnage or bottoms for transportation facilities is responsible. On the other hand, to quote another well-informed concern, the main cause of the advances is the great uncertainty with which the whole situation is surrounded and the difficulty of securing reliable information as to output and shipment. Late last week importers were advised by cable of "limits" on Straits tin for May or June shipments; but there were more buyers than sellers. Another source of trouble is that shipping permits are not being readily granted by the British government.

Some consumers, reports say, have been placing orders for more than their real requirements, and it is estimated that if a quarter or even a half of these purchases are held up by permits enough will come through to keep them supplied. As it stands, there is neither Straits nor Banca spot tin in the market, and very little Chinese, with sellers holding out for the highest possible price. All that can be bought is on shipments which are likely to arrive several months hence.

Tin plays a very important part in the electrical and allied supplies market. Condensers are either coated with tin or they are made of an amalgam of tin and copper. Boiler tubes are also tin-lined, and if a substitute equally good were not made this would cause a serious predicament for central stations. All copper wire to be rubber-covered is first coated with pure tin. If this metal continues to be scarce and high, an early advance in the price of rubber-covered wire must naturally follow, in the opinion of a prominent manufacturer. At present, to use the statement of the same authority, the entire cost to the producer is from 3 to 5 per cent. So far this increased cost has not been passed along to the jobber, dealer or consumer.

Were tin to become still more expensive or to be unattainable, a coat of pure Para rubber, said an expert, could be used on the copper wire, but this process would increase the price of rubber-covered fully 50 per cent. As yet that branch of the industry has not been called upon to meet this emergency. The concern in question supplies a majority of the rubber-covering factories with tinned wire. For lack of sufficient tinned stock a number of these plants have already been obliged to close down. Tin is also extensively used in certain grades of trolley wire. For weatherproof wire employed in the neighborhood of acid or other factories, where the presence of sulphur fumes corrodes and destroys the insulation, the core is likewise submitted to a tinning bath, as in the rubber-covered variety.

Wherever solder is utilized, as in the manufacture of dry batteries, tin is an important element. So far the consumption is not so great as to affect prices on the finished goods. The metal is also employed in everything of brass, bronze, phosphor-bronze, babbitt metal for journal bearings, and in other alloys known in the trade. It is the general belief, therefore, among producers of merchandise in which tin is a factor that, while current prices have not yet been revised on account of the shortage, discussion along these lines is arousing unusual interest and serious attention.

DIFFERENTIAL BASIS OF COPPER-WIRE PRODUCTS

Reason Why Manufacturers with Accumulated
Copper Stock Are Quoting Lower Prices—The
Jobber's Position in the Market

Lower prices have been looked for by the trade on all copper-wire products for some time. This belief was founded on the quotations for base, which have been gradually receding to present quotations of 27 to 30 cents. When a large wire manufacturer was asked why the price was growing lower in the face of the government or officially established selling figures of 23.50 cents for car lots and 27.67½ cents for less than car load—prices which still prevail and have been extended by the War Industries Board to June 1—he said that the causes were various.

First, quite a stock of copper had been accumulating in the hands of primary buyers, and the market was therefore softening. Then commercial manufacturers who had a stock of high-price copper on hand had gradually worked it off. Conditions had been about equalized. Therefore it was possible on special business to sell wire on a 27-cent base.

Small sizes of wire and cable were still figured and sold on a 30-cent base. Where 27 cents was quoted it was either to meet competition or because of a desire to secure business. In transactions of this kind the credit standing of the customer is the principal factor. On some contracts taken at 27 cents base it is a matter of discounts. Orders at this figure have been accepted at 60 per cent off; others at 60 and 5, and again still others at 60 and 10 to large buyers. Orders for more than \$10,000 are figured from cost and a margin of profit ranging from 10 to 25 per cent. Purchasers of large quantities of signal wire, like the prominent railroads, buy on a 23-cent base.

The general average, however, to quote this and other authorities, is a 30-cent base. This figure is quoted to jobbers buying from manufacturers, with a discount of 60 per cent. On orders under \$2,500 the usual discount is 50 per cent. It depends very much upon the commercial rating of the buyer. Sometimes an additional profit may be added for carrying the customer. Rubber-covered, lead, varnish, cambric and paper-insulated materials are sold on a cost

basis plus a profit, which, of course, varies with the customer. There is no regular or hard and fast rule. Weather-proof is selling on an established pound basis, which is now 27 cents. One manufacturer states that all list prices are based on lengths of 250 ft. of one size and kind. For shorter lengths add to list price 20 per cent on lengths up to 100 ft., 10 per cent on 100 ft. to 250 ft.

Large sizes of wire are now selling almost to the exclusion of the small sizes. The sale of the latter has fallen off on account of the almost total suspension of building operations. The government is taking the greater portion of every manufacturer's output. Originally these purchases were made by the wire cable committee of the Committee of National Defense. Within the last four months the shipyards have been buying direct on a competitive basis. They are now the most important outlet for wire products.

STEADY DEMAND DEVELOPING FOR COAL-CRUSHING APPARATUS

Manufacturers Meet a Necessity Occasioned by the Acute Fuel Situation—Cogent Reasons Pre- sented for the Existing Demand

Manufacturers report that coal-crushing apparatus is enjoying a steady demand of considerable volume. There are several reasons for this. First, attention has been called to the very serious waste of fuel unless it is properly sized to burn on ordinary stokers. Second, the acute coal situation has made it necessary for coal buyers to take any kind of coal they could get, whereas in the past they might demand some particular grade or size of coal. This makes it necessary to install crushing apparatus at the plant of the consumer. Third, the manufacturers of crushing apparatus have ceased to devote their energies to trying to convert the coal mines themselves to the necessity of crushing coal and have turned their energies toward the more fertile field of the coal user. All these factors have contributed to build up a healthy demand for coal-crushing apparatus.

METAL MARKET SITUATION

Copper Deliveries Are Causing More Anxiety than Price—Shortage of Tin Prevails

Views on the copper market differ widely. Professional commentators are inclined to be pessimistic and urge an increase of the official price. Consumers, particularly in the industrial field, are calmly awaiting developments and buying as they need. As one wire manufacturer of high reputation says, copper is not so easy, in fact, is difficult, to obtain. That is to say, the metal can be bought, but the question is when will it be delivered. This company never buys less than 500,000 lb. at a time and frequently five times that quantity, and it usually keeps in reserve 2,000,000 lb. No change of price has occurred in rubber-covered cable or weatherproof wire. Tin is the shining mark in the metal market and a shortage that may be serious is imminent.

THE WEEK

IN TRADE

MAMMOTH orders for electrical equipment, accessories and supplies are the notable feature in this week's trade. This means the government is the buyer for the various enterprises turning out war material. Shipyards, cantonments, munition factories and similar auxiliary plants are being fitted up electrically, and the result is something of a scarcity of goods for strict commercial purposes. The demand is heavy for motors, wire, cable, conduit, lamps, etc. Eastern factories report a shortage of material for the Western trade.

Deliveries may be slightly better, but many complaints of car facilities are mentioned. This is partly explained by an official report, which, while covering the Eastern territory, is evidently applicable to other parts of the country. The statement says the poor supply of both open-top and box cars is becoming very serious. More than 10,000 carloads of material has been manufactured and is waiting transportation, being held up on account of an insufficient car supply. The situation during the last week has become more acute.

On Monday the War Industries Board put the final crimp in building operations. All new construction work, by the order promulgated, will have priority assistance withheld in the supply and shipment of material of every description unless it contributes to winning the war. The action of the board brings into existence the expected division of industries into essentials and non-essentials.

Collections are being looked after closely, with the general average rated from fair to prompt. Credits receive close attention, and extensions are placed on a short schedule.

NEW YORK

With the milder weather and freight conditions improving, the trade in general is responsively submitting reports of greater activity. To be sure, this applies to the dominating market influence—namely, government requirements—in which jobbing houses of recognized stability and standing are participating. On commercial sales jobbers report business a trifle quiet, but the factory situation is excellent. It may be described as a steady movement on electrical goods, especially in household specialties. New price lists on a higher level become effective in some lines April 1.

Financial obligations are being met with commendable promptness. Credits are tightening.

FRACTIONAL-HORSEPOWER MOTORS.—The demand for these goods is strong, and to meet the requirements of the market one widely known manufacturing company is devoting the entire facilities of one of its large plants exclusively to the production of fractional-horsepower motors. The average size is 0.5 hp., with 86 to 90 per cent special types, coming as small as 0.02 hp.

SOCKETS AND RECEPTACLES.—An advance of from 10 to 20 per cent was made this week in several types of standard porcelain sockets and receptacles. The revised prices become immediately effective.

PORCELAIN.—Knobs, cleats, bushings, rosettes, tubes, insulators and all other porcelain lines will go out under a revised price list, probably on higher quotations, April 1, according to a preliminary notice to this effect transmitted to the jobbing trade last week by a manufacturer who operates a chain of plants. This attitude is reflected by local conditions, bearing out the belief of a marked shortage.

COLLECTIONS AND CREDITS.—With every allowance for dealers being disinclined to settle accounts until goods held up by embargoes are actually delivered, collections are stated to be satisfactory. Credits, however, are tightening up quite generally.

CROSS-ARMS.—The situation has not bettered to any great extent, deliveries interfering greatly with filling orders. On an order for 40,000 cross-arms 16,000 were delivered, the remainder being in transit. A distributor of prominence recently circularized central stations advising them to place orders early for spring requirements out of stock. Recently an advance of from 12 to 15 per cent was announced, due to an increase in the workmen's wages.

GLASS INSULATORS.—As predicted, the government's tremendous quantity specifications have absorbed stock and shortened production for general sale. Manufacturers report no anticipated price increase.

MOTORS.—No lessening is noted in the call for motors of medium sizes, and the second-hand market is looked over for needed machines. As an instance of this a correspondent writes the *ELECTRICAL WORLD* as follows: "About two years ago we bought a certain 75-hp. slip-ring (280-volt) motor in Philadelphia for \$550. Three months ago our customer sold this to a dealer in our city for \$1,425, who in turn sold it for use in Trenton, N. J., for \$1,675, the customer paying an additional fee for trucking from Newark."

TELEGRAPH AND WIRELESS INSTRUMENTS.—An unusually brisk demand by the government is in evidence for these instruments. A manufacturer who is also a leading jobber reports that his factory has been running overtime on orders.

BELLS AND GONGS.—Sales are increasing, but no change in price has occurred or is looked for. Eastern jobbers are in a favorable position for goods.

CONDUIT.—Conduit continues to be extremely short. As previously observed, quantities are in transit but their whereabouts is simply guesswork. Consequently shipments arrive in the most erratic manner and not in sufficient quantities to ease the market. There is a strong demand for export, but of types unknown to the American trade. Jobbers say it is puzzling to grasp what is actually wanted.

CHICAGO

Orders are coming in in good volume. Prices are firm. Buying is of a steady nature, such as is to be expected in a market where the prices of basic commodities are staple. Deliveries in some lines are not so good as might be desired, but on the whole this situation is improving. Observers believe that better business may be expected as spring comes on.

In Chicago the electrical permits for the week ended March 20 aggregated 573 permits, amounting to 8598 lamps and 1717 hp. This is an increase over the previous week, with 543 permits, amounting to 6810 lamps and 1208 hp. It is less than the same week last year, in which 826 permits were issued. The record of building permits follows: Week ended March 20, 59 permits, \$692,800; same week year ago, 180 permits, \$2,473,600; previous week, 51 permits, \$256,100.

CONDUIT.—Deliveries are still in a state of "no promise." Jobbers who have complete stocks are lucky. There are probably not more than three complete stocks in Chicago. Nearly all have some ½-in. conduit, but the larger sizes are in strong demand with a very limited supply. Manufacturers in quoting deliveries to jobbers say, "We will ship in two weeks if we can get the cars," or "if there is no embargo." Prices are steady.

WIRE.—Weatherproof wire is showing activity, indicating some improvements and extensions by central stations. While there have been no actual changes in prices, an advance is expected on account of the high price of cotton. One wire manufacturer recently could have sold his stock of cotton at a price to net him more than he could have made on the wire it would insulate. He refused because he has customers to supply. It is reported that the American Electrical Works have changed their way of basing weatherproof wire. Formerly the common practice was to include all sizes from No. 8 to No. 4/0 as base sizes. This company, it is said, now includes sizes No. 6 to 4/0 only as base sizes. This is in effect an increase in price, since now 1 cent is added to the base for No. 8 and 2 cents for No. 10, whereas No. 8 was formerly included in the base.

CROSS-ARMS.—Cross-arms have taken an advance that amounts to about 25 per cent. The large amount of fir being used in aeroplane manufacture is given as the cause for the increase.

POLES.—All sorts of wooden poles are reported to be slackening in demand. Some pole producers are turning their attention to getting out large quantities of piling, which is in strong demand.

VENTILATING FANS.—The demand for ventilating fans and blowers has increased greatly in the last few months, especially for use in industrial plants. The demand, however, has not been so great in new building operations as it has been in old ones. A large number of the orders coming in to manufacturers in the city ask for immediate shipment, and the manufacturers are taking steps to have an extra supply of equipment on hand.

BOSTON

War industries continue to absorb the output of electrical energy and manufactures to a degree hitherto unknown. The shock of the great conflict in France produces fluctuations in security quotations, but seems only to stimulate New England business and productive resources to a more intense determination to do everything possible to rid the world of autocratic militarism. Stocks of equipment suited to factory and shipyard service are low in comparison with house and mercantile establishment reservoirs. Prices are holding firm, with no recorded changes of moment in this district in the past week. Labor conditions are more settled than for some time. Collections are closely followed, and the trade acceptance plan is now being utilized by some of the more progressive jobbing interests to the great advantage of the trade. Labor-saving appliances are moving well.

The Central Maine Power Company has just purchased a 2000-kw. generating unit for use in a new hydroelectric plant which is under construction in the Waterville district. The demand for power in the Maine shipyards is now much in excess of former requirements. Central stations in general continue to maintain a conservative policy regarding extensions, but if a way could be found to secure material at somewhat lower cost this practice of "sitting on the lid" might perhaps be replaced by one of greater enterprise. Deliveries are still conditioned largely upon the railroad situation, which improves gradually, though hardly fast enough to suit the Eastern buyer.

HOUSEHOLD APPLIANCES.—Considerable interest is displayed by the public in washers, flatirons and vacuum cleaners. One Boston retailer states that the first quarter of 1918 will show a sale of the lighter equipment, including flashlights, lamps and dry batteries, within 20 per cent of the best three months' sales in the past decade. Transient trade is good in retail circles. Toasters are moving well at Portland, Me., considering the size of the territory.

SECOND-HAND MACHINERY.—Trade continues brisk. For the moment some motors of larger size are on the market, and a prominent house reports a good stock of transformers.

STORAGE BATTERIES.—A heavy government business is being handled, and stocks are below normal for the general trade. Prices remain steady. Orders have been booked for portable, hand-controlled battery-lighting sets for trench service, for auxiliary lighting on destroyers and other government service of great importance. Industrial electric truck applications are now quite a factor in the battery business.

PORCELAIN.—Despite the protracted lull in house wiring considerable shipments of porcelain fittings are going into the smaller cities.

CONDUIT.—Stocks are running lower and the railroad situation, combined with other demands upon the mills, is giving local distributors many uneasy hours. A Portland jobber recently shipped conduit to New Haven, Conn., and to New Jersey from a stock accumulated before the present disturbed conditions became fully felt. The government appears to be getting the lion's share of the pipe at this time.

ATLANTA

The tone in building circles is decidedly more cheerful, despite the unusual and in some respects unprecedented handicaps under which construction operations are now carried on. There is, of course, much construction of an absolutely necessary character that will be done this year, which will include increased facilities at military establishments, shipyards and long-delayed residential work. Approximately \$1,000,000 will be expended at Montgomery, Ala., to build and equip a plant for repairing aeroplanes. This will further stimulate the demand for staple electrical supplies, which have been put on a standard basis owing to the past activity in this class of material. The necessity for greater economy in textile production is evidenced by the fact that a number of mills are discarding heavy group drive for more refined equipment in the way of four-frame and individual motors. Contracts for equipment of this nature have been closed this week by W. A. Handley Mills, Roanoke, Ala.; Woodruff Mills, Woodruff, S. C., and Brandon Mills, Greenville, S. C.

HEATING CORD.—While the market was more active during the past few months, jobbers report, however, that trade is holding up fairly well. Deliveries are good.

TAPE.—The volume of sales is very heavy, and the rising price of cotton, which is reflected in the price of this material, does not appear to deter buying. Stocks are in good shape to handle the situation.

CONDUIT.—A stimulated trade in both the black and white rigid products over the last few weeks, together with a decline of approximately four points in price, are the main features to be noted in this line. Shipments show a marked improvement, dropping back to three to four weeks.

ARMORED FLEXIBLE CABLE.—Trade in this line has lagged appreciably, owing to the fact that speculative building in apartments, etc., and old-house wiring have slowed up. No difficulty is experienced in supplying isolated requirements, as a substantial stock of this material is on hand. Prices are off slightly.

STAMPED STEEL BOXES.—This line has shown sluggish tendencies of late, as the present activity in conduit for industrial purposes, as compared with other building construction, precludes the call for outlet boxes. Prices remain firm and deliveries have been comparatively good.

AUTOMOBILE SUPPLIES.—Answers to inquiries for this line indicate a big business, with an ever-increasing volume of sales, the only difficulty being to deliver the goods. Charging outfits and spotlights are going fine, the delivery in these being fair. The activity in miniature lamps shows no abatement, but they are exceedingly hard to get and the demand for deliveries is very discouraging. Jobbers are doing their utmost to satisfy requirements by shipments that are in short supply.

SEATTLE

The volume of business during the week was heavy, but not marked by any startling developments. Sales to shipyards showed a slight increase, particularly in the Portland field, where buying is being completed for the new plants. Government buying is noticeably lighter. Several jobbers report the arrival of delayed shipments of schedule materials and domestic appliances. Sewing machines especially continue moving rapidly and stocks are very low. Recent shipments were used to fill long-standing orders. Several projected concrete shipbuilding plants in the Puget Sound territory are commanding considerable attention. Inquiries for electrical equipment for the proposed plants were recently received. The Alaska engineering commission of Seattle on March 25 opened bids for the largest order it ever placed for rubber-covered wire, insulators, cable, conduit, condensers, etc.—eighty-five classes of material in all.

Seattle's building records for the first three months of the year, if maintained, will result in the construction of three times as many homes this year as last, and will equal, if not pass, the record of 1909, when permits for nearly 4000 homes were issued. Portland reports state that building has taken a sudden spurt.

Authorities at the American Lake cantonment, Tacoma, forwarded recommendations for new construction totaling \$1,146,000 to Washington, D. C. The proposed extensions include barracks, storage and other buildings, etc. Secretary McAdoo wired the Chamber of Commerce and the Commercial Club that he would do his best to have Pacific Coast car builders bid on car requirements. A record yield of wheat is predicted in eastern Washington. Elevators are being erected in large numbers equipped with electric lighting systems and operated by electric equipment. The present shortage of farm labor is expected to become acute. Lumber mills have advised the spruce production bureau that unless freight cars are furnished to move the surplus lumber the mills will have to close down.

Electrical jobbers report extreme difficulty in securing materials except those used for government contracts, unless priority certificates are secured. Even priority certificates do not insure prompt delivery, as certificates must come in order. Jobbers report heavy orders for sewing machines, washers and like domestic appliances en route. Large-size wire and circular-mill cable orders are heavy from shipbuilding concerns, and materials are difficult to obtain. Eastern factories are making slow deliveries. Government orders have decreased noticeably in the last two weeks. Prices are holding up well with stocks poor.

The consumption of lamps is increasing, with no proportionate increase in the output. All sizes are in demand, and jobbers are having difficulty in filling more pressing orders. It is hoped the new daylight saving law and the completion of the addition to the Oakland Lamp Company's plant in California, which supplies Pacific Coast jobbers, will afford a measure of relief. There is an extreme shortage of a certain type. Shipyards and government orders predominate, although orders for new residence construction and remodeling are large. There is a noticeable increasing demand for porcelain cleats and tubes for shipyard and residence work. Stocks are maintained better than could have been expected under present freight conditions.

SAN FRANCISCO

For the first time in many weeks building reports show a return to normal conditions in that they principally consist of private construction and alterations. Bungalows, houses and apartment buildings replace the now familiar industrial work. There is little improvement in deliveries from the East, the average time required for a carload being close to fifty days, which time was formerly halved with ease. Nor is this the only source of delay. Eastern factories report a shortage of material and inability to get cars. Once a car is started westward it seems to get caught in a sort of whirlpool in the great transfer points, such as Chicago and Kansas City, and disappears from its tracers for days at a time. Naturally on the Pacific Coast, which is at the end of the government's transportation system and a jobbing instead of a manufacturing district, this congested condition is felt keenly by contractors and dealers. Private building has been practically at a standstill for many weeks and electrical contractors in the larger cities have been depending upon industrial work or on pumping plant business. In the interior the dry winter has not been detrimental to them.

Central stations, the Pacific Gas & Electric Company and the Great Western Power Company have petitioned the railroad commission for its authority to increase their rates about 15 per cent, claiming that the increased cost of labor and material and the need of auxiliary forces to offset the decreased rainfall render it absolutely necessary to increase their receipts. A prominent power company recently estimated an average increase of 60 per cent in cost of material used for pole-line construction. The result is that new construction is practically non-existent. Medical apparatus dealers everywhere report an increased sale for such devices as vibrators, medical batteries and even violet-ray machines, but are unable to agree on its cause. More intensive advertising and sales efforts are partly responsible, but an unusual amount of sickness created by a peculiar winter is the chief reason. Hospital equipment manufacturers report many inquiries.

Current Prices of Electrical Supplies

New York and Chicago Quotations

THE prices quoted are those prevailing in standard packages of specified lots on apparatus and appliances in Eastern and Middle West markets at the beginning of business on Monday of this week. They are in all cases the net prices or prices subject to discounts from standard lists of contractors, central stations, dealers and others engaged in the resale of such goods.

Prices in Southern and other nearby markets will rule about the same as those in the Middle West, although slight modifications to cover increased freight and local demands should be expected. In the Far West and on the Pacific Coast the prevailing prices are naturally higher, covering as they must increased

freight and the necessity of larger stocks with increased interest and warehouse charges on account of the distances from sources of supply, infrequent turnover of stock and uncertainty as to delivery of goods in transit. Moreover, the Far West presents a wide variation in demand due to a small population spread over a wide area in agricultural and mining communities, as contrasted with the denser population of the East and Middle West, their nearness to the sources of supply, the more frequent turnover in stocks and the constant demands which arise in industrial centers. Price variations may be due to difference in grade of products of different manufacturers, to local conditions, or to both.

NEW APPARATUS & APPLIANCES

A Record of Latest Developments and Improvements in Manufacturers' Products Used in the Electrical Field

Reverse Current Relays for Circuit Breakers

A reverse-current relay that will open either upon reversal of current or with zero current at abnormally low voltage is illustrated herewith. The relay

REVERSE-CURRENT RELAYS FASTENED TO
REAR OF CIRCUIT-BREAKER PANEL

is closed and held closed by a shunt polarizing coil. A high resistance is connected in series with the polarizing coil to limit the current in holding the relay closed. To close the relay, a push-button switch is provided which temporarily short-circuits the high resistance. These relays are designed for mounting on the rear of circuit-breaker panels and are manufactured by the Automatic Reclosing Circuit Breaker Company of Columbus, Ohio.

Contact-Resistance-Heated Electric Soldering Iron

The Clemens Electric Corporation, Buffalo, N. Y., has improved its electric soldering iron, which was described in the June 23, 1917, issue of the *ELECTRICAL WORLD*. One of the principal changes has been the provision of an

INSULATED HANDLE PREVENTS BURNING
OF WORKMEN'S HANDS

insulated handle on the movable lever which is employed to close and open the circuit. The copper-pointed iron is held against the two carbon contacts shown in the accompanying illustration by a steel strip spring. The heat is produced

by the contact resistance where the carbon electrodes touch the iron. The device is efficient, it is claimed, because it heats only when the iron is in contact with the work and then heats almost instantaneously.

Battery-Charging Outfit

The Hobart Brothers Company of Troy, Ohio, has recently brought out the large-size battery-charging outfit shown in the accompanying halftone. The unit is rated at 2 kw. and is capable of charging thirty-two batteries at one time. The load box, shown in the illustration, will permit any load from minimum to maximum rating and will take care of any intermediate values necessary. The machine, which is self-starting, can be used to charge differ-

OUTFIT CAPABLE OF CHARGING DIFFERENT-
VOLTAGE BATTERIES AT THE SAME TIME

ent-voltage batteries at the same time. It is fool-proof, and no special electrical or mechanical knowledge is necessary to operate it.

Large Electric Range

The Rutenber Electric Company of Marion, Ind., has built the range shown herewith, which it is said is one of the largest single-section ranges ever built. The Rutenber double cloverleaf type of air-cooled terminal heating unit or hot plate is used throughout this range. There are twelve of these hot plates, of which eight are rated for 1000 watts and four for 1500 watts. All hot plates are equipped with three heat switches. These hot plates are placed six on each side of the ovens.

There are two large ovens, each 14 in. by 16 in. by 18 in. (35.6 cm. by 41.6 cm. by 46.7 cm.), and two smaller ovens 10 in. by 16 in. by 18 in. (25.4 cm. by 41.6 cm. by 46.7 cm.). Each of the

ovens has two heating elements, one above and one below. The upper ones are rated at 375, 750 and 1500 watts. The lower ones are rated at 200, 400 and 800 watts, giving fifteen different combinations of heat in each oven.

The ovens are lined with aluminumized steel and are equipped with a

EACH UNIT IS INDIVIDUALLY FUSED AND
EASILY ACCESSIBLE

Rutenber standard door catch and thermometer. The range has each unit individually fused, the fuses being easily accessible. There is a designation strip between the fuses and the switch which shows the unit that the set of fuses or switch controls. There are two lamp-socket attachments on the range. Three warming closets and one large warming oven with two doors are furnished. This range has a maximum connected load of 23,200 watts.

Safety Inclosed Switches

The Krantz Manufacturing Company of Brooklyn, N. Y., is manufacturing a line of safety auto-lock switches for use as main-circuit switches and wherever the knife switch is ordinarily needed. The accompanying illustration shows the working side of the switch, which consists of brush-type contacts and an operating switch handle. The use of this brush-type contact prevents the surface becoming welded together owing to slow closing and therefore increases safety to the circuit. The brush contact is made directly with the incoming terminal block and fuse terminal block, thus elimi-

SAFETY SWITCH PREVENTS CONTACT WITH
LIVE TERMINALS

nating all splices, soldering, joints and unnecessary connections. When it is desirable to replace the fuses in the switch the handle is locked shut.

When the front door of the box is opened it is impossible to come in con-

act with the live parts of the circuit. The advantage of this feature is apparent when it is considered that non-electrical men are usually employed in steel mills or industrial plants. The stationary contacts are of hard-drawn copper, and the fuse block terminals are mounted on a plate base.

The double-ended brushes cause a double break in each circuit, dividing the arc between the two ends. Each end is provided with a separate arcing tip. In the closed position the switch is held in positive contact by a toggle over the center. In opening the switch a spring provides very quick break, the mechanism working independent of the operating handle. It is claimed that these switches will carry their 150 per cent rated current without undue heating. The device has been approved by the National Board of Fire Underwriters.

Projectors

The Luminous Unit Company of St. Louis, Mo., has developed a projector equipment which is designed for use on standard type "C" lamps. A simple focusing arrangement is provided by means of which it is possible to adjust the beam of light from a narrow search-light beam to a wide flood, as conditions may require. This adjustment is external and may be made in a moment's time. The reflector is of metal, highly polished and permanent. The units are ventilated and waterproof under any conditions, it is claimed. The front lens is of polished wire plate glass.

Three sizes are available, from 200 watts to 1000 watts rating, which range provides for ordinary requirements. The projectors are arranged for mounting on $\frac{3}{4}$ -in. (1.9-cm.) iron pipe.

Oil-Submerged Compression Cut-Out

A re-fusable cut-out which combines both the compression and the oil-submersion principles is illustrated herewith. The cut-out is adapted for both overhead and subway service and can be used on lines operating at 2000 volts to 4000 volts with a 10-amp. to 200-amp. duty. The fuse element is held between compression blocks which are

COMPRESSIVE ACTION OF REFRACTORY BLOCKS "SNUFFS OUT" FUSE ELEMENT

made of refractory material. When the fuse element becomes overheated it will soften, and as it yields the compression action of the blocks tends to extinguish the arc. All of the working parts are immersed in oil and therefore an arc,

if formed, will be choked off by the action of the oil and also chilled and extinguished by the contact of the compression blocks. The explosive action of the arc is also greatly reduced. The box is held tightly closed by four heavy claws, which can be drawn in around the rim or released by a handle. The plug member can then be removed from the cut-out box when it is desired to replace the fuse element. The device is being marketed by the G. & W. Electric Specialty Company, 7440 South Chicago Avenue, Chicago.

Cold-Flowed Cable Terminals

The Mutual Electric & Machine Company of Detroit, Mich., has placed upon the market a cable terminal or soldering lug that is made by the "cold-flowed" process from a solid copper rod. The accompanying illustration of two different views of the completed terminal shows clearly the construction of the lugs. The terminal is made by cutting the solid copper bar into slugs and placing them in a machine which causes

CABLE TERMINAL MADE OF ONE PIECE

the material to flow into the upper half of the terminal while cold. Then the remaining solid portion is flattened or spread out and pierced. These operations are performed while the material is cold, and therefore the material is not ruptured. For this reason the terminal cannot leak when it is filled with solder. The bottom portion of the hole is flat, so that a minimum amount of solder is used. After the socket is filled with solder and the cable inserted a positive joint is assured between the cable and the terminal. At the present time the lugs are constructed to carry currents up to and including 200 amp.

Wire Supporter and Insulator

The accompanying illustration shows a wire supporter and insulator manufactured by the L. F. Manufacturing Company of 426 Hoboken Avenue, Jersey City, N. J. These wire supporters and insulators are made of soft malleable iron and are designed to support and clamp duplex or single-wire alongside of poles and other surfaces. They are especially adapted for service wires and cut-ins for buildings, lamp

services, etc. This device eliminates the use of tie wires and does not injure the original wire insulation. The fittings are interchangeable, as only a few parts have to be in stock to cover a wide range of work. The insulators,

INSULATOR THAT AVOIDS USE OF TIE WIRES

which are made with either conical or round ends, shed water, snow or ice readily.

Automatic Control for High-Rated Electric Furnaces

The accompanying diagram shows an arrangement whereby variable voltage operation of three-phase electric furnaces can be accomplished by changing the high-voltage connection. The high melting voltage is obtained by connecting the high-voltage windings in delta and the lower refining voltage by connecting them in star. During the melting period variable voltage is obtained by means of high-voltage taps and external reactance is provided to be cut in during this melting period. The furnace is equipped with a three-section control panel containing three shunt relays and three contactor groups. Contact-making ammeters are also provided with dash-pots to prevent hunting of the electrode motor, and the coils are provided with taps which are used to vary the amount of power supplied to the furnace. Each contactor group consists of three units all mechanically interlocked, two contactors being normally open and the other being nor-

DIFFERENT HEATS OBTAINED BY CHANGING HIGH-VOLTAGE CONNECTIONS

mally closed. The motor for operating the electrodes is dynamically braked so that all moving parts may be stopped instantaneously. The installation as described is manufactured by the General Electric Company.

Trade Notes

J. D. BARNHILL, INC., has changed its name to the Dodd-Dubosque Company, Inc., with offices as before at 110 West Thirty-fourth Street, New York City.

THE GREENLEAF COMPANY of Boston, Mass., announces the occupancy of an entire floor in the new Christian Endeavor Building, 41 Mount Vernon Street.

J. H. SROUFE and S. C. Jaggard of Portland, Ore., have organized the Jaggard-Sroufe Company and have opened offices in the Pittcock Block as electrical contracting engineers. Special attention will be devoted to marine and mill work.

FRED B. DUNCAN has been appointed manager of the Chicago office of the Packard Electric Company of Warren, Ohio. Mr. Duncan was formerly assistant chief engineer of the power and light plant of the International Harvester Company.

F. W. JESSOP, formerly works manager of the Electric Controller & Manufacturing Company, Cleveland, Ohio, has formed the Ohio Electric & Controller Company, 5900 Maurice Avenue, Cleveland, to manufacture lifting magnets and controlling devices.

THE H. W. JOHNS-MANVILLE COMPANY of New York City has opened a new branch office at 1015 A Street, Tacoma, Wash. There is carried a complete stock of asbestos packings, molded and in sheet form, and other well-known Johns-Manville power-plant specialties.

THE AMERICAN CHAMBER OF COMMERCE of the city of Mexico has issued the first number of the *Journal of the American Chamber of Commerce*. It is illustrated and contains information of interest to manufacturers desiring to market their products or better their trade connections in Mexico.

THE GLOBE ELECTRIC COMPANY of Milwaukee, Wis., announces the opening of an office of its company at 106 North La Salle Street, Chicago, to take care of its electric farm lighting and storage-battery business. W. R. Patton, sales manager of the company, has announced that this office will be in charge of G. M. Gardner.

THE INTERNATIONAL TEXTILE, INC., of Bridgeport, Conn., announces that the business heretofore known under the name of Alb. & E. Henkels, Inc., will hereafter be conducted under the name of International Textile, Inc. H. A. Philips will remain as general manager. The company recently supplied the government with a quantity of insulating tape.

ARTHUR ORGAN of New York City has taken the agency of the "Laun-dry-ette," an electrically operated washing machine manufactured by the Home Specialty Company of Cleveland, Ohio. Mr. Organ, whose office is at 114 Liberty Street, will inaugurate a sales campaign to assist dealers and central stations, whereby his salesmen will help in creating consumer demand.

WALDEMAR D. HERRMANN, for the past two years special representative of the C. J. Netting Company of Detroit, Mich., has joined the forces of the Holophane Glass Company as district agent for Michigan, northern Ohio and New York. Mr. Herrmann was special representative for the Johns-Manville Company for four years, and also was with the Sunlight Company.

THE WAR TRADE BOARD JOURNAL of Washington, D. C., will hereafter be issued regularly on the first day of the month. From time to time, however, as occasion may warrant, special issues will be published devoted to particular phases of the work of the board. In the middle of March it was proposed to bring out a special number, which was to include live matter of interest to exporters and importers.

THE DINGLE-CLARK COMPANY has been organized with offices at 536 Engineers' Building, Cleveland, Ohio. This corporation will handle a complete line of motors, transformers, controllers and turbo-gears. Howard Dingle and W. W. Clark were, up to Feb. 1, respectively district manager and assistant manager of the Crocker-Wheeler Company in Cleveland. Both have been in the Ohio territory for the past ten years.

THE BATTERMAN-TRUITT COMPANY, formerly of 18-20 East Kinzie Street, Chicago, has removed its offices and factory to 736-738 West Monroe Street. The new factory is about three times as large as the old one. The reason for the move was mainly for more room for stocking up equipment for immediate shipment. This company manufactures ventilating fans,

blowers, etc. H. E. Batterman is president, E. Ackerman vice-president, and J. E. Truitt secretary and treasurer.

THE STANDARD ELECTRIC & ELECTRIC COMPANY of Baltimore, Md., is completing a new and larger plant at 118-120 East Pratt Street. When finished it will have floor space of about two acres. An exhibition and salesroom, with shipping department in rear, will occupy the first floor. The entire second floor will be devoted to the offices. The coil-winding department is on the third floor, with the "baking" room and blueprint sections, and the machine and repair shops are on the fourth floor.

Trade Publications

GUY-WIRE ANCHORS.—W. N. Matthews & Brothers, Inc., of St. Louis, Mo., is circulating a post card describing the Matthews "Scrulix" anchor.

METAL STATISTICS.—The eleventh annual edition of "Metal Statistics" is ready for distribution by the American Metal Market Company of 81 Fulton Street, New York.

METAL PRODUCTS.—The American Steel & Wire Company has issued a daily desk calendar, one side of every page being devoted to notices regarding products made by this company.

TAPS, DIES AND REAMERS.—W. L. Brubaker & Brothers of 50 Church Street, New York, have issued catalog No. 4, entitled "Taps, Dies and Reamers." The book is well illustrated and also contains price lists.

LIGHTING FIXTURES.—The title of catalog No. 20 issued by the Indesco Lighting Fixtures Company of 47 Warren Street, New York City, describing its lighting fixtures, shades, floor and portable lamps.

PRESSURE GAGES.—The Ashton Valve Company of 161 First Street, Cambridge "C," Boston, Mass., is distributing circular No. 100 on "master-pilot" pressure gages. The bulletin describes the double-illuminated pressure gage.

SAFETY INCLOSED SWITCHES.—The Kranz Manufacturing Company has issued a circular covering its safety auto-lock inclosed switches. A clear description of the switch, showing its advantages, together with illustrations, is given in the circular.

AIR COMPRESSORS.—The Ingersoll-Rand Company of New York City has published a vest-pocket booklet describing its products and giving a list of the uses of compressed air. Valuable engineering data and information are also presented in the booklet.

BOILERS.—The Engineer Company of 17 Battery Place, New York, has issued two bulletins, Nos. 16 and 18, on balanced draft. The booklets give the theory and application of balanced draft to practice with descriptions of apparatus manufactured by the Engineer Company.

TELEPHONE SYSTEMS.—The Swedish Electric Telephone & Manufacturing Company of Chicago has issued catalog No. 32 of the apparatus that it manufactures. The catalog is well illustrated and shows switchboards of various types and other necessary apparatus for complete telephone systems.

RAILROAD ELECTRIFICATION.—The Westinghouse Electric & Manufacturing Company of East Pittsburgh, Pa., is circulating a bulletin entitled "The Further Prospect of Railroad Electrification." A discussion of the cost and advantages of railroad electrification is made in the bulletin.

PORTABLE ELEVATORS.—The New York Revolving Portable Elevator Company of 343 Garfield Avenue, Jersey City, N. J., is distributing a 1918 calendar referring to its revolving portable elevator, called the "revolator." Illustrations showing applications of this mechanism are produced on the calendar.

INCLOSED SWITCHES.—The Trumbull Manufacturing Company of Plainville, Conn., is circulating a booklet describing its "Circle T" inclosed switches. This bulletin shows the inclosed knife switches, both externally and internally operated, in bent-up steel and cast-iron boxes. Prices of the switches and their parts are listed.

PIPE TOOLS.—The Greenfield Tap & Die Corporation of Greenfield, Mass., has issued catalog No. 38, showing its complete line of pipe tools. The booklet also contains miscellaneous tables of information that are very valuable for pipe and drill-size calculations. The corporation is also circulating

ing a booklet which gives the history of the company.

WIRE SUPPORTERS AND INSULATORS.—The L. F. Manufacturing Company of Jersey City, N. J., is distributing a catalog describing its duplex wire supporters and insulators. The booklet is well illustrated and shows pole-type and house-type brackets, wire supporters and insulators for supporting wire along the sides of poles and other surfaces.

FARM LIGHTING PLANT.—The Sackett Company of Columbus, Ohio, in a bulletin on the "Sackett Hyrax Farm Lighting Plant" illustrates a farm lighting unit it is making. Photographs of various houses lighted by the Sackett system are shown, and the lighting fixtures and appliances that complete the installation are also illustrated in the catalog.

ELECTRIC HEATING DEVICES.—The Simplex Electric Heating Company, 85 Sidney Street, Cambridge, Mass., is distributing a bulletin and price list of its electric heating devices. The bulletin includes bake ovens, boilers, chafing dishes, circulating-water heaters, curling-iron heaters, disk stoves, fry kettles, glue pots, griddles, heating pads, hot closets, hot plates, heater cord, immersion coils and various other heating devices.

INDUSTRIAL RESEARCH AND DEVELOPMENT.—Esterline & Angus of Indianapolis, Ind., have issued a booklet giving a record of some engineering and industrial research and development work that they have carried out. The title of the booklet is "A Unique Service by a Unique Organization." A few suggestions showing why an independent consulting engineering organization is better than the ordinary engineering department are given.

New Incorporations

THE MUNICIPAL ELECTRIC LIGHT & POWER COMPANY of Henderson, Ill., has been incorporated with a capital stock of \$1,000 by Jesse H. Baker, Edna M. Baker and A. S. Button.

THE NORTHWOOD-KENSETT ELECTRIC COMPANY of Northwood, Iowa, has been chartered with a capital stock of \$50,000. E. H. Dwells is president and M. H. Kepler secretary.

THE ATWATER (OHIO) LIGHT & POWER COMPANY has been incorporated by E. P. and P. W. Whittlesey, C. A. Cummings and N. W. Brockett. The company is capitalized at \$10,000 and proposes to construct and operate an electric-light plant.

THE OHIO ELECTRIC COMPANY of New York, N. Y., has been incorporated by J. Milburn, Jr., D. E. Masten and W. J. Nelson, 1463 Broadway, New York, N. Y. The company is capitalized at \$100,000 and proposes to deal in electric and mechanical appliances for household use.

THE DOUGLASS (PA.) TOWNSHIP ELECTRIC COMPANY has been chartered with a capital stock of \$5,000 to furnish electrical service in Douglass. The incorporators are: Theodore M. Dame of Boyertown, Clinton H. Miller and William Maulmeasy, both of Philadelphia, Pa.

THE WASHINGTON (PA.) TOWNSHIP ELECTRIC COMPANY has been chartered by William Maulmeasy and Clinton H. Miller, both of Philadelphia, Pa., and Theodore M. Dame of Boyertown, Pa. The company is capitalized at \$5,000 and proposes to furnish electricity for lamps, heaters and motors in Washington.

THE INTERNATIONAL ENGINEERING & MANUFACTURING COMPANY has filed articles of incorporation under the laws of the State of Delaware with a capital stock of \$1,000,000 to install electric-light and power plants. The incorporators are: S. B. Howard, George V. Reilly and A. W. Britton, all of New York, N. Y.

THE COLEBROOK TOWNSHIP ELECTRIC COMPANY of New Berlinville, Pa., has been granted a charter with a capital stock of \$5,000 to supply electricity for lamps, heaters and motors in New Berlinville. The incorporators are: Theodore M. Dame of Boyertown, William Maulmeasy of Philadelphia, Pa., and Clinton H. Miller of Philadelphia, Pa.

THE OHIO ELECTRIC & CONTROLLER COMPANY, 5900 Maurice Avenue, Cleveland, Ohio, has been incorporated with a capital stock of \$200,000. The company proposes to manufacture lifting magnets immediately and controlling devices later. The officers are: T. W. Jessup, president; W. B. Greene, vice-president, and A. D. Walter, secretary and treasurer.

New England States

CONCORD, N. H.—The Contoocook (N. H.) Electric Light Company has applied to the City Council for permission to erect electric transmission lines through the city of Concord from the town of Hopkinton to the town of London. If given permission to enter the town the company agrees not to furnish electricity in this city or to bid for the local lighting contract.

CLINTON, MASS.—Contracts have been awarded by the State Commission for the installation of gates and motors to utilize the waste water running over the spillway of the Wachusett dam to develop additional power.

FALL RIVER, MASS.—The stockholders of the Fall River Electric Company have voted to petition the Gas and Electric Light Commissioners for permission to increase the capital stock of the company from \$1,400,000 to \$2,100,000. The proceeds are to be used to take up outstanding indebtedness and also for the new high-tension transmission system that is to be erected over the Taunton River.

SPRINGFIELD, MASS.—Contracts have been awarded by the Undertakers' Supply Corporation, Stearns Building, Springfield, for the erection of a new power house, 25 ft. by 30 ft., in connection with a large new plant at East Springfield. Gour Brothers, 20 Woodmont Street, are the contractors.

WORCESTER, MASS.—Surveys, it is reported, are being made by the New England Power Company of Worcester for the erection of the proposed high-tension transmission line from Millbury to Webster.

BRIDGEPORT, CONN.—Contract has been awarded by the Remington Arms Union Metallic Company for an addition to one of the buildings, 61 ft. by 417 ft., at its cartridge plant.

Middle Atlantic States

BUFFALO, N. Y.—The Frontier Water Steam Supply Company, 667 Main Street, has increased its capital stock from \$40,000 to \$150,000, the proceeds to be used for expansion purposes.

BUFFALO, N. Y.—The plant of the Western Electric Equipment Company, 66-70 Broadway, was damaged on March 14 by fire, causing a loss of about \$40,000. The company manufactures electrical supplies, etc.

BUFFALO, N. Y.—The Delaney Forge & Iron Company, 300 Perry Street, Buffalo, is planning to make extensions to its forge plant at Perry Street and the Lehigh Valley Railroad, including the erection of a large building, 130 by 300 ft., and a machine shop, 100 by 250 ft., one story.

DUNKIRK, N. Y.—Arrangements are being made by the Board of Water Commissioners and the City Council for the installation of an ornamental street-lighting system in a portion of the business district, standards carrying a single lamp instead of cluster lamps. It is understood, will be used. W. O. Peck is superintendent of the municipal electric-light plant.

LOCKPORT, N. Y.—The Public Service Commission has authorized the Lockport Light, Heat & Power Company to issue \$106,700 in capital stock, the proceeds to be used to take up outstanding indebtedness.

NEW YORK, N. Y.—The Public Service Commission has granted the Union Railway Company permission to build an extension of its Fordham Road-205th Street cross-town line to Dyckman Ferry.

NEW YORK, N. Y.—The Interborough Rapid Transit Company is planning to build a new one and three-story transformer station on Seventy-fourth Street, near Avenue A, to cost about \$12,000.

NEW YORK, N. Y.—The Mexican Telegraph Company has purchased a site on Broad Street from South William to State Street. The company, it is said, will erect a building on the site, at a cost of about \$400,000.

NEW YORK, N. Y.—Plans have been filed by George H. Pegg, chief engineer of the Interborough Rapid Transit Company, for the erection of a three-story transformer station, 40 ft. by 41 ft., on Seventy-fourth Street, east of Avenue A, to cost about \$12,900.

PEEKSKILL, N. Y.—The Weehawken (N. J.) Dry Dock Company has acquired about 760 acres at Verplank's Point, formerly owned by the Hudson River Brick Manufacturing Company, the C. I. Bleakley Company and others. The company, it is understood, will erect a shipbuilding plant on the site, to cost about \$3,000,000, to be equipped for the construction of steel, concrete and wooden ships. The company now has a plant at the foot of Baldwin Street.

Construction

News of Projects, Plans, Bids and Contracts. Notes on Work Under Way

ROCHESTER, N. Y.—The Wheeler-Greene Electric Company, 31 St. Paul Street, Rochester, has increased its capital stock from \$100,000 to \$500,000, the proceeds to be used for extensions to its plant.

ROCHESTER, N. Y.—The Public Service Commission has granted the Rochester Railway, Light & Power Company permission to issue \$2,000,000 in capital to cover the cost of recent improvements in the equipment of its Genesee River hydraulic plant. The company has also petitioned for authority to issue \$4,000,000 additional capital stock.

SAND LAKE, N. Y.—The McLaren Knitting Company has applied to the Town Board for a franchise for the erection of an electric transmission line to enable it to secure electricity from the Albany Southern Railroad Company to operate its mills in Sand Lake.

SYRACUSE, N. Y.—Plans have been filed by the Crouse-Hinds Company, Seventh, North and Wolf Streets, Syracuse, for the erection of a new two-story plant, to cost about \$800,000. The company manufactures electrical goods.

SYRACUSE, N. Y.—Plans have been filed by the Swan & Finch Company, 416 Tracey Street, for the construction of an addition to its power station. Contract for the work has been awarded to Frank M. Kimmey, 1007 West Onondaga Street.

WATERTOWN, N. Y.—The Northern New York Utilities, Inc., has petitioned the Public Service Commission for permission to issue \$480,000 (par value) in bonds and \$223,000 in capital stock, the proceeds to be used for the proposed 5000-hp. development at Black River and 1800-hp. at Effley Falls on the Beaver River, to provide power for war and munitions purposes, already covered by contracts.

YONKERS, N. Y.—Plans have been filed by the National Sugar Refining Company for the erection of a new power plant, 90 ft. by 140 ft., at its works at the foot of Main Street.

BRIDGETON, N. J.—The installation of a new municipal electric-light plant is under consideration by the City Council.

JERSEY CITY, N. J.—The General Storage Battery & Repair Company is planning extensions and improvements to its plant.

JERSEY CITY, N. J.—The proposed plant to be erected by Henry Ford on the meadows near Jersey City for the construction of submarine chasers will consist of a fabricating shop, a fitting-out shop and three assembling plants. The cost of the plant is estimated at about \$3,000,000, and it will adjoin the works of the Ford Automobile Company.

PATERSON, N. J.—The Ordnance Department, Washington, D. C., is negotiating for the property at Clay Street and Madison Avenue, Paterson, on which it proposes to erect a number of buildings for the use of the Ordnance and Quartermaster's Departments, to cost about \$2,000,000.

TRENTON, N. J.—Plans have been completed by the city for the erection of a new power house in connection with another building to be located at the Municipal Colony in Hamilton Township. William Kleman of Trenton is architect.

HARRISBURG, PA.—Application has been made to the Public Service Commission by the Bernville Light, Heat & Power Company, the Penn Mills Light, Heat & Power Company and the Jefferson Light, Heat & Power Company for approval of their incorporation and for permission to begin the exercise of rights, power, franchises and privileges within the boundaries of Berks County.

PHILADELPHIA, PA.—Contract has been awarded by the estate of B. Jones for the construction of a new boiler plant at Sixty-fourth and Lebanon Streets.

PITTSBURGH, PA.—Plans have been filed and contract awarded by the South Pittsburgh Water Company, Carrick, for the construction of a new power plant, 45 ft. by 115 ft., to cost about \$35,000. The Walker & Curley Company, E. E. Trust Building, Pittsburgh, is contractor.

PORTERSVILLE, PA.—Plans have been prepared by the Fox Coal Company of Brannan, near Portersville, for the construction of a new power house at its works. Charles D. Hall, Jenkins Arcade, Pittsburgh, is engineer.

READING, PA.—Notice has been filed with the Public Service Commission by the Metropolitan Edison Company of an issue of \$25,000 in bonds, the proceeds to be used for improvements, etc., to its plant and system.

BALTIMORE, MD.—The Baltimore Manufacturing Company is planning to erect a power plant and cooper shop at Central Avenue and Bank Street, Baltimore.

BALTIMORE, MD.—The Sapero Box Company, 220 East Grindall Street, Baltimore, is planning to establish a wood-working factory at 2501 Boston Street. About 300 hp. in motors, it is understood, will be installed.

BALTIMORE, MD.—The City Council has passed the ordinance authorizing the Washington, Baltimore & Annapolis Electric Railway Company to build additional connecting tracks for the operation of an extension to its freight terminal facilities.

BALTIMORE, MD.—Plans are being prepared by the Baltimore Manufacturing Company, Monument and Constitution Streets, for the erection of a new power station at Central Avenue and Bank Street, in connection with other extensions at its works.

HAVRE DE GRACE, MD.—The Havre de Grace-Taneytown Electric Railway Company, recently incorporated, is contemplating the construction of an electric railway from Havre de Grace via Towson, Finksburg and Westminster to Taneytown, a distance of about 65 miles. C. Stanley, 423 Calvert Building, Baltimore, is president.

MORGANTOWN, W. VA.—The court has authorized the issue of \$60,000 in receiver's certificates for repairs and improvements on the Morgantown & Wheeling Railway.

ALEXANDRIA, VA.—Final plans and specifications have been prepared by Frederick T. Ley, Springfield, Mass., for the construction of a shipbuilding plant at Jones Point for the American Shipbuilding Company. The work will include the construction of six shipyards, fabricating shop, 212 ft. by 400 ft., one story; machine shop, 75 ft. by 200 ft.; blacksmith shop, two stories, 60 ft. by 125 ft.; joiner shop, two stories, 60 ft. by 125 ft.; tin and copersmith shop, 50 ft. by 125 ft.; carpenter shop, 60 ft. by 150 ft.; storehouse, 75 ft. by 250 ft.; water and sewer system; power for six shipyards, trackage, etc. The Fred T. Ley Company, 495 Main Street, Springfield, Mass., are engineers and contractors.

PINCASTLE, VA.—The Roanoke & Botetourt Telephone Company has filed notice with the Public Service Commission of an increase in capital stock from \$10,000 to \$15,000, the proceeds to be used for extensions, etc.

WASHINGTON, D. C.—Contract has been awarded to the Turner Construction Company, 241 Madison Avenue, New York, N. Y., by the United States government for the construction of a new underground distributing system and power plant at G and Twenty-fifth Streets, to cost about \$550,000.

WASHINGTON, D. C.—Bids will be received at the Bureau of Yards and Docks, Navy Department, Washington, D. C., until April 8 for furnishing and installing exciters, switchboards, cell structures, cell equipment, wiring, transformers and other miscellaneous electrical power plant equipment in power plant at the navy yards at Norfolk, Va., and Philadelphia, Pa. Drawings and specifications No. 2762 may be obtained at the above bureau or of the commandant of the navy yards named.

WASHINGTON, D. C.—Bids will be received at the Bureau of Supplies and Accounts, Navy Department, Washington, D. C., for furnishing at the various navy yards and naval stations supplies as follows: Brooklyn, N. Y., Schedule 1748—7000 ft. leaded and armored, soft-steel galvanized, 32-conductor interior-communication cable; 15,000 ft. plain, single-conductor lighting and power wire. Hingham, Mass., Schedule 1752—one 2-ton electric truck. Philadelphia, Pa., Schedule 1751—two motor-driven, back-sawed 16-in. extension-base shapers. Application for proposal blanks should give the schedule desired by number.

WASHINGTON, D. C.—A bill has been reported to the House of Representatives asking for appropriations for the naval service for the year ending June 30, 1919. The work contemplated includes improvements to the power plant at the navy yard, Portsmouth, N. H., at a cost of \$150,000; improvements to the central power plant at navy yard, Boston, Mass., \$75,000; improvements to the central power plant at Philadelphia, Pa., \$300,000; improvements to central power plant and distributing system, Norfolk, Va., \$300,000; central power plant and distributing system at the Naval Academy, \$325,000; improvements to the central power plant and distributing system at the naval station,

New Orleans, La., \$280,000; Improvements to central power plant and distributing system at navy yard, Mare Island, Cal., \$100,000; Improvements to central power plant and distributing system at the navy yard, Puget Sound, Wash., \$200,000, and the installation of telephone and transmission system at naval station, Guantanamo, Cuba.

North Central States

DEARBORN, MICH.—Plans are under way for the construction of a large plant for manufacturing and assembling of Fordson tractors at Dearborn. The cost of the plant is estimated at \$3,500,000, and when completed it will employ about 100,000 men. Among the buildings to be erected are: A foundry, 120 ft. by 225 ft.; stock room, 30 ft. by 100 ft.; heat treating room, 40 ft. by 145 ft.; assembling shops, 44 ft. by 165 ft. and 44 ft. by 105 ft.; pattern shop, 50 ft. by 105 ft.; gas producer plant, 54 ft. by 45 ft.; power plant, 70 ft. by 45 ft.; two machine shops, 75 ft. by 285 ft. and 90 ft. by 225 ft., respectively. The plant is located across from the Ford blast furnaces.

GRAND RAPIDS, MICH.—The Grand Rapids Salvage Company, it is reported, is furnishing structural steel and reinforcing for power house for the Haskolite factory at Fuller Station.

IRON MOUNTAIN, MICH.—Contract has been placed for the installation of a complete electrically-operated pumping plant for the water-works system. The city has entered into a contract with the Peninsula Power Company for electrical energy.

KALAMAZOO, MICH.—The Leonard Tractor Company is reported to be contemplating the construction of a plant in Kalamazoo, to cost with equipment about \$300,000.

AKRON, OHIO.—Plans are being prepared by the Northern Ohio Traction & Light Company for the erection of new warehouses, laboratory, club house and other buildings in Akron, to cost about \$200,000.

AKRON, OHIO.—In a decision recently handed down by the Supreme Court of the United States the city of Akron is given the right to build a dam across the Cuyahoga River and divert water from the stream for power purposes. The city was opposed by the Cuyahoga Power Company.

COLUMBUS, OHIO.—Improvements are being made to the municipal electric-light plant involving an expenditure of about \$365,000. The city is changing all arc lamps except magnetite to 400-cp. nitrogen-filled lamps and is installing 700 additional 400-cp. nitrogen-filled lamps at a cost of about \$60,000. New equipment includes two 500-hp. water-tube boilers and one 5000-kva. Allis-Chalmers two-phase, 2200-volt turbo-generator. The city is also erecting two substations. Lewis Rowe is acting superintendent.

SPRINGFIELD, OHIO.—The Springfield Light, Heat & Power Company, it is reported, has awarded contract for two 500-hp. Babcock & Wilcox boilers, to be installed in the new addition to its plant.

YOUNGSTOWN, OHIO.—The Trus Con Steel Company is planning to build an addition to its plant. The main building will be 30 ft. by 400 ft. Considerable new equipment, it is understood, will be required.

GRAHAM, KY.—The W. G. Duncan Coal Company of Greenville is planning to build a power house, 75 ft. by 100 ft., and erect from 4 to 5 miles of transmission line, to connect Greenville, Luzerne and Depoy. All material and equipment, it is understood, has been purchased.

ATTICA, IND.—The municipal electric-light and water plant was destroyed by fire on March 9.

BLOOMINGTON, IND.—Bids will be received by the board of trustees of the Indiana University, at the office of R. F. Daggett & Company, architects, Lemcke Annex, Indianapolis, until April 8 for the construction of two buildings as follows: (1) Building for the Indiana University School of Medicine; (2) power house and laundry for Indiana University School of Medicine. For building, separate bids will be received on general contract, heating, ventilating, plumbing, elevator, electrical work and vacuum cleaning apparatus. For power house and laundry, separate bids will be received on general contracts, electrical equipment, ice-making and refrigerator machinery, radial brick stack, plumbing, including tunnel between the buildings, wiring, piping, etc. Plans and specifications are on file in the office of the architects and at the office of John W. Cravens, secretary of board of trustees, Bloomington.

HAWTHORNE, ILL.—Plans are being prepared by the Western Electric Company of Chicago, Ill., for the construction of a new factory building, 211 ft. by 675 ft., six

stories high, at Forty-second Avenue and Twenty-second Street, to cost about \$1,000,000.

HOMER, ILL.—The Homer Electric Light & Power Company is contemplating extending its electric transmission lines to Fairmount. The company recently made connections with Sidney.

ROCKFORD, ILL.—The proposal to issue \$500,000 in bonds for the purpose of establishing a municipal electric-light plant will be submitted to the voters at the April election.

ROCKFORD, ILL.—Contract has been awarded by the Rockford Motor Club for construction of power house and pumping station, in connection with the erection of a new club house.

EAU CLAIRE, WIS.—Plans have been prepared by Foeller & Schober, Green Bay, for the construction of a boiler house and laundry plant, 40 ft. by 95 ft., for the Sacred Heart Hospital at Eau Claire.

MADISON, WIS.—Bids will be received by M. E. McCaffrey, secretary of the University of Wisconsin, Administration Building, University of Wisconsin, Madison, until April 15 for the construction of the Mary Cornelia Bradley Memorial Hospital and Infirmary Buildings of the University of Wisconsin. Plans and specifications may be obtained at the office of secretary upon deposit of \$10 for each building.

MILWAUKEE, WIS.—Bids, it is understood, are being asked by the Fraser Company, 667 East Water Street, Milwaukee, for the construction of an elevator and storehouse at Oregon and Hanover Streets, to cost about \$200,000, for the L. Tewels Seed Company, 113 Clybourn Street, Milwaukee. New equipment, including electric motor, conveying machinery and tank, etc., will be required.

CROSBY, MINN.—At an election he'd recently the proposal to issue \$76,000 in bonds for the installation of an electric-light and power plant was carried.

HINCKLEY, MINN.—The Hinckley Electric Lighting Company, it is reported, is planning to rebuild its lines between Hinckley and Sandstone.

IONA, MINN.—The installation of a municipal electric-light and power plant, to cost \$10,000, is under consideration.

WILLMAR, MINN.—The contract for electrical work in connection with alterations and additions to the high school building has been awarded to Sterling Electric Company, 33 South Fifth Street, Minneapolis.

BOYDEN, IOWA.—The Board of State Railroad Commissioners has granted Veen-schoten Brothers of Boyden a franchise to erect and operate electric transmission lines on certain roads and highways in Sioux County for a period of 25 years.

DUBUQUE, IOWA.—Improvements will be made to the power plant at the local railroad shops of the Chicago, Milwaukee & St. Paul Railroad Company, involving an expenditure of about \$50,000.

HAMBURG, IOWA.—Orders have been placed by the Hamburg Electric Light Company for material and equipment for the installation of an entire new street-lighting system, including a new tub regulator, transformer and switchboard panel, all new hoods for street lamps, new poles and standards. All lamps will be hung in the center of the street intersections and all goosenecks will be removed.

GARDEN CITY, MO.—The local electric plant, owned by Kaufman & Son, is reported to have been purchased by the Green Light & Power Company of Pleasant Hill. The new owners, it is understood, will erect an electric transmission line to Garden City soon.

OSARK, MO.—The Ozark Coal & Mining Company is contemplating the purchase of power plant, coal-mining machinery, etc., to cost about \$6,000. M. V. Waterfield is secretary and manager.

GRAND FORKS, N. D.—Bids will be received by Charles Leissman, secretary of State Board of Regents, for the construction of a chemistry building at the State University at Grand Forks. Separate bids to be submitted as follows: (1) General contract; (2) steam heating and ventilating; (3) plumbing; (4) wiring. Plans and specifications are on file at the office of Charles Leissman, secretary of board, Bismarck, at the business office of the University, Grand Forks, and at the Builders' Exchange in Grand Forks, Bismarck and Fargo, N. D.; St. Paul, Minneapolis and Duluth, Minn., and Chicago, Ill.

BLACKWELL, S. D.—At an election held recently the proposal to issue bonds for improvements to the municipal electric-light plant and waterworks system was carried.

MILLER, S. D.—The City Council is considering calling an election to submit the proposal to issue \$30,000 in bonds for a

municipal electric-light and power plant and \$15,000 for water-works system to the voters.

SHERMAN, S. D.—The Village Board has granted Blm Brothers a franchise to supply electricity for lighting the streets and residences in Sherman.

FALLS CITY, NEB.—Contracts have been awarded for equipment for the municipal electric-light plant as follows: For engines to the Nordberg Manufacturing Company of Milwaukee, Wis., at \$28,000; generator and switchboard to the B-R Electric Company of Kansas City, Mo., at \$16,051. All bids on condenser equipment were rejected. Specifications will be revised and new bids called for soon.

LINCOLN, NEB.—The Board of Control has awarded the contract for construction of a new power house at the penitentiary to R. W. Stake of Lincoln, at \$3,280. The new building will replace the old structure on the west side of the prison inclosure, which will be torn down.

LINCOLN, NEB.—The State Board is considering the advisability of connecting the State House with the local electric-light plant for emergency service. The Lincoln Traction Company has offered to erect a connecting line from Twelfth and K Streets to connect with the line from the penitentiary plant if the State will pay \$250 to cover the expense of erecting the line and pay the regular rates for energy for emergency service.

LINCOLN, NEB.—The State Board of Irrigation has canceled the application of J. F. Johnson of Milford for a power site on the Blue River, south of Crete, and has allowed the petition of H. B. Babson of Chicago, Ill., for same site. The latter has filed a bond for \$1,000 to begin work on construction within six months. Mr. Babson is interested with Burdette Boyes of Seward in several power sites along the Blue River.

OMAHA, NEB.—The contract for electric wiring for the new telephone exchange of the Nebraska Telephone Company has been awarded to the Edwin C. Bennett Electric Company, City National Bank Building, Omaha.

SCHUYLER, NEB.—Preliminary plans are being prepared by the Electrical Development Company of Sioux City, Iowa, for improvements to the municipal electric-light plant. A bond election, it is expected, will be called soon.

CANEY, KAN.—Notice has been served on the Kansas Light & Power Company, which owns and operates the local plant, that unless repairs are made to its plant and the service greatly improved the city will take over and operate the system. The electric plant was burned down about a year ago and since then has been taken over by the above company.

EL DORADO, KAN.—The City Commissioners have decided to extend the ornamental street-lighting system.

GARDNER, KAN.—The City Council has under consideration the installation of a municipal electric-light plant. A statement made by Mr. Bushong, an engineer of Ottawa, concerning the cost of establishing a plant here with an electric transmission line places the cost at about \$17,000 and with a power plant at approximately \$21,000. A committee has been appointed by the Council to make investigations and report at the next meeting.

LARNED, KAN.—The City Council is considering extending the electric transmission lines of the municipal electric-lighting plant to neighboring towns to supply electrical service.

LURAY, KAN.—Preparations are being made for improvements to the municipal electric-light plant, including the purchase of new equipment and construction of new power house. Bids for the proposed work, it is understood, have been received.

RANDOLPH, KAN.—The Council has adopted an ordinance authorizing a contract with the Riverside Light & Power & Gas Company for lighting the streets of Randolph with electricity.

SALINA, KAN.—The Robinson Milling Company has awarded the general contract for construction of mill and elevator to the Eberhardt Construction Company. Two buildings will be erected, one 36 ft. by 100 ft., six stories, and the other two stories, 36 ft. by 100 ft., at a cost of about \$250,000.

SALINA, KAN.—Contract has been awarded by the Shellabarger Mill & Electric Company to the Eberhardt Construction Company for the construction of an addition to its mill, 54 ft. by 70 ft., two stories high, including electric wiring, complete refrigerating apparatus, etc. The cost is estimated at \$150,000.

WESTMORELAND, KAN.—H. Holden, representing the Riverside Light & Power Company of Abilene and of the Rocky Ford plant, has submitted a proposal to the

local business men offering to extend its electric transmission lines to Westmoreland and furnish electrical service, provided the city will pay the expense of building the proposed line.

Southern States

FOREST CITY, N. C.—The Alexander Manufacturing Company, recently organized with a capital stock of \$200,000, is planning to erect a mill to manufacture hosiery yarn. The proposed mill will be equipped with 10,000 spindles and with electrically-driven machinery. R. C. Biberstein of Charlotte, N. C., is architect.

TY TY, GA.—At an election held recently the proposal to issue \$7,000 in bonds for the installation of a municipal electric-light plant was carried.

VALDOSTA, GA.—Extensive improvements are contemplated at the Ocean Pond club house, including the installation of an electric-light plant to supply electricity for lighting the house and grounds.

COLUMBIA, TENN.—Steps have been taken by M. R. Sterns of Nashville and associates to organize a company, to be capitalized at \$200,000, to construct and operate an electric generating plant on the Duck River near Columbia. The plans provide for a 10,000-hp. development.

BIRMINGHAM, ALA.—The Birmingham Tidewater Railway Company is contemplating extending its railway from Pratt City to Ensley, a distance of 3 miles.

CHICKASAW, ALA.—The Chickasaw Shipbuilding Company is planning the construction of an electric generating plant, to cost about \$750,000, in connection with its \$10,000,000 shipbuilding plant now under construction.

COLUMBIA, ALA.—Work has begun on the enlargement of the Omsussee plant of the Columbia Power Company, to cost about \$500,000. The company, it is reported, is contemplating establishing a plant at Kelson, to cost approximately \$500,000. Tucker & Laxton of Charlotte, N. C., have charge of the work at the Omsussee.

VICKSBURG, MISS.—A 1500-kw. turbine, it is reported, is being installed in the plant of the Vicksburg Light & Traction Company.

DELIGHT, ARK.—The Council has granted B. F. Ryon of Texarkana a franchise to construct and operate an electric-light plant in Delight.

HELENA, ARK.—Extensions, including the installation of additional machinery, it is reported, are under consideration by the Helena Gas & Electric Company.

STUTTGART, ARK.—The erection of a grain elevator is reported to be under consideration by the Stuttgart Flour Mills.

TEXARKANA, ARK.—The city of Texarkana is planning to equip a sewage disposal and pumping plant, to cost about \$140,000. L. T. Peden of Houston, Tex., is consulting engineer.

JENNINGS, LA.—Extensions to the electric-lighting system are under consideration by the City Council.

BRISTOW, OKLA.—At an election held recently the proposal to issue \$6,000 in bonds for the purchase of the local electric-light plant and installing an ornamental street-lighting system throughout the city was defeated.

FERGUSON, OKLA.—The Elaine County Salt Company, it is understood, will require considerable electrical equipment in connection with a new salt plant.

LAVERNE, OKLA.—The city has taken over the plant of the Laverne Light, Power & Ice Company, to be owned and operated by the municipality.

MIAMI, OKLA.—Local business interests, it is reported, have subscribed \$200,000 toward the construction of the proposed electric railway from Miami to Picher and other mining towns.

MUSKOGEE, OKLA.—Contract for the construction of the long-discussed Grand River dam, it is reported, has been awarded to L. S. Skelton of Oklahoma City. The proposed hydroelectric power plant will generate electricity to be distributed in Muskogee and other cities within a radius of 50 miles.

OKMULGEE, OKLA.—Plans are being prepared by Burns & McDonnell, Kansas City, Mo., Interstate Building, for improvements to waterworks and pumping plant and sewage disposal plant, to cost about \$150,000.

RYAN, OKLA.—Plans are being considered for the installation of a crude oil engine in the municipal electric light and water plant.

SAPULPA, OKLA.—The contract for the electrical work for the new high school building has been awarded to the Electrical Contracting Company of Tulsa. The cost of the building complete is estimated at \$200,000.

DENISON, TEX.—The installation of a municipal electric-light plant in Denison is under consideration.

FORT STOCKTON, TEX.—The Pecos & Rio Grande Telephone Company is contemplating extending a telephone line into Loon Valley, on which work will begin as soon as material can be procured.

FORT WORTH, TEX.—The Missouri, Kansas & Texas Railway Company, it is reported, will rebuild its local coal chute, recently destroyed by fire. F. Ringler of Dallas is chief engineer.

GRAND SALINE, TEX.—The three buildings being erected by the Grand Saline Salt Company will be equipped with vacuum pans, pumps and engines for refining salt by the vacuum tank method.

McKINNEY, TEX.—The Texas Light & Power Company, it is reported, will rebuild the local electric-light plant, recently destroyed by fire, causing a loss of about \$8,000.

Pacific and Mountain States

BELLINGHAM, WASH.—The stock and equipment of the Mills & Larson electric store at 1331 Dock Street has been purchased by the Modern Electric Company, 13.2 Dock Street. Both stores will be operated at present, but later the retail store will be removed to the location formerly occupied by Mills & Larson and the store at 1322 Dock Street will be converted into a battery station and electric repair shop. The contracting business of Mills & Larson will be continued.

CHENEY, WASH.—Preparations are being made by the F. M. Martin Grain & Milling Company for the construction of an 800-barrel flour mill to replace its present mill. A five-story building, equipped with a 15,000-bushel elevator, to cost about \$85,000, will be built.

SEATTLE, WASH.—The Rothert Process Steel Company is contemplating an addition to its smelter (100 ft.) and the installation of a 10-ton electric furnace. The offices of the company are located at 622 Harriman Street, Seattle.

SPOKANE, WASH.—Negotiations will soon be under way for a new general street-lighting contract. It is proposed to replace the present arc-lamp lighting system with nitrogen-filled lamps.

TACOMA, WASH.—The City Council has decided to submit the proposal to issue \$4,000,000 in bonds by which the city of Tacoma will secure a new power plant at the city election to be held on April 16. The ordinance provides that the Council shall select the site for the plant, the work to be done by either the "cost plus 10 per cent" plan or by force account; it also provides for offers from holders of power sites for the sites and completed power stations, together with transmission lines to the city. No bid will be considered on a site and station that will not develop 22,000 kw. regularly and 30,000 kw. in a six-hour stretch every day. Several offers have been submitted to Commissioner H. F. Gronen, including the Lake Cushman site and the Packwood Lake site in Lewis County. Portland parties have offered to build a plant at an unnamed site for \$3,900,000.

IONE, ORE.—The Jordan Elevator Company of Corvallis is contemplating the construction of an elevator at Ione, with a capacity of 100,000 bushels, to cost about \$35,000.

KLAMATH FALLS, ORE.—The California-Oregon Power Company of Klamath Falls has been appointed by the federal authorities as agency to make a survey of southern Oregon and northern California. A military map is being prepared to outline the company's work in this section.

PORTLAND, ORE.—A permit has been granted to the Northwestern Electric Company, Pittock Building, for the erection of a building at the foot of Lincoln Street, to cost about \$15,000.

LOS ANGELES, CAL.—Arrangements, it is understood, have been made by the City Council for financing the project and awarding contract for the installation of the new ornamental lighting system for Broadway.

SAN DIEGO, CAL.—An appropriation of \$750,000 has been made by the United States government for the construction of a naval aeronautical academy at North Island, San Diego. The plans provide for a department for building and repairing aeroplanes, etc. The cost is estimated at about \$2,000,000.

GRANGEVILLE, IDAHO.—Work is under way on the construction of a large dam on Clearwater River, 8 miles from Grangeville, which when completed will double the output of the present plant. The dam is in circular form, 400 ft. long and 20 ft. high, and, it is estimated, will develop about 1600 hp.

SALT LAKE CITY.—Application has been filed with the State Engineer by G. R. Corey of Salt Lake City for permission to use 125 ft. of water from Price River to develop about 1600 hp. The proposed plant would be located within a few miles of Helper and would involve the construction of a concrete dam, 3 ft. high and 40 ft. long, the water to be conducted in a ditch for a distance of 1½ miles, passing two 4-ft. wheels, under an 85-ft. head.

HARLEM, MONT.—The contract for the installation of the new ornamental lighting system in Harlem has been awarded to the Electric Construction Company of St. Paul, Minn., at \$4,550.

MANVILLE, WYO.—The installation of a new electric-light plant in Manville is reported to be under consideration. The cost is estimated at \$30,000.

WHEATLAND, WYO.—The contract for the new equipment for the municipal electric-light plant has been awarded to the Fairbanks-Morse Company. A new 150-hp. fuel oil engine and a 120-kw. generator, directly connected, and a new switchboard will be installed.

MONTROSE, COL.—The ordinance granting the Western Colorado Power Company a new 20-year franchise to operate in Montrose has passed its first reading in Council.

COLUMBUS, N. M.—The Columbus Electric Light & Power Company, it is reported, contemplates the construction of an electric-light and power plant to supply electricity in Columbus and Camp Furlong. The cost of the proposed plant is estimated at about \$30,000.

Canada

PINCHER CREEK, ALTA.—The town of Pincher Creek is considering the installation of an oil-burning engine and a 50-kw. generator in the municipal electric light plant, provided it can dispose of the present equipment, which is too large for the size of the town. H. Bossenberry is chairman of light committee.

MURRAYVILLE, B. C.—The British Columbia Electric Railway Company has begun work on equipping the new Laking mill for electrical operation and will extend its service in this section, installing lighting systems in several residences and large ranches.

VANCOUVER, B. C.—The contract for electrical work in connection with remodeling the Wallace shipyards has been awarded to the Mudy, Rowland Company. The entire power system will be reconstructed.

COBDEN, ONT.—Plans are being considered to raise the storage dam of the Cobden light and power plant about 2 ft., to enable the plant to furnish a 24-hour service during the dry season. G. A. Parr is treasurer.

OTTAWA, ONT.—Tenders will be received by John A. Pearson, architect, and J. O. Marchand, associate, Center Block, Parliament Buildings, Ottawa, until April 11, for electric wire and cable for the reconstruction of the Parliament buildings. Specifications and other information may be obtained at the office of P. Lyall & Sons Construction Company, Ottawa.

GRAND'MERE, QUE.—The construction of an electric railway from Grand'Mere to Shawinigan Falls, to cost about \$100,000, is under consideration by the business men of both places.

Miscellaneous

PANAMA.—Bids will be received at the office of the general purchasing officer, the Panama Canal, Washington, D. C., until April 11, under Circular 1206, for furnishing electric elevators, scales, etc.

PANAMA.—Bids will be received at the office of the general purchasing officer of the Panama Canal, Washington, D. C., until April 11, for furnishing electric elevator, scales, copper, pipe covering. Blanks and further information relating to this circular (1208) may be obtained from the above office or at the offices of the assistant purchasing agents, 24 State Street, New York, N. Y., 606 Common Street, New Orleans, La., and Fort Mason, San Francisco, Cal.

Private Capital Needed for Water-Power Development

THAT was an admirable statement made by Secretary Lane before the House water-power committee in Washington last week. No clearer statement appears in the record of the hearings, and we might add no saner. It is necessary that there should be real development of our water-power resources, and that soon. All are agreed as to that, and all are agreed that every safeguard should be thrown around the public and the government. As for the investor, that is another matter on which there are varying opinions. In the opinion of the Secretary of the Interior, all water-power propositions are gambles, and for that reason any one putting money into a hydroelectric project has got to have very real consideration. He is a developer, a pioneer who takes a risk, and for that risk he ought to be compensated. It certainly is futile in the present emergency to enact legislation which will bring no results. If private capital is sought for hydroelectric work, those with money to invest naturally are interested in the rate of return such securities will command. If investments in equivalent enterprises bring greater returns, money will flow in that direction, and there will be no development of water powers by private capital. The rate of return which will attract capital to hydroelectric utilities is a determinable fact, and Congress should make an honest effort to ascertain it. If determined correctly, the money for these hydroelectric enterprises will be forthcoming, and if the rate is too low it will not. The only way to get results and get them promptly is to be liberal; the surest way to check development is to be niggardly. The whole question of water-power development simmers down to a choice between these two, and on the present Congress rests the decision.

Concord in War Labor Program

THE liberal labor program laid down last week by the war labor conference in its report to Secretary Wilson, if rightfully observed, will prove a boon to war industries, which now include many electrical manufacturing companies. Its vital sections should be read by every laborer and employer in the country, and we trust the fairness of these sections will commend themselves to both alike. Certainly organized labor has conceded its strongest weapon, the right to strike, and it is inconceivable that capital shall refuse to make sacrifices comparably as great. If maximum production is to be obtained, and nothing short of that will

suffice to win the war, there must be no lingering reservations in the mind of either labor or capital. By and large, employers have co-operated whole-heartedly in every movement suggested by the national government for the successful prosecution of the war. Labor has not been one whit less patriotic, although there have been honest differences between labor and capital on the means for effecting the end. Now that a working agreement between them has been reached, greater outputs should accrue, and who can tell but that the beneficent work of co-operation will extend for a period long after the war has ceased?

Conservation Versus Efficiency in Lighting

THE paper by A. L. Powell on lighting curtailment in the industries is one deserving very serious consideration. It is a sad fact that in many instances the Fuel Administration has been raising a lamentable cloud of smoke for a very little effective fire. It seems to have traveled on the theory that to produce the requisite psychological effect conservative statements should be abandoned in favor of scare headlines. The unfortunate results of this policy are very clearly shown in Mr. Powell's presentation of the case. The effect has been in certain instances to produce frantic attempts at economy which have seriously cut down the efficiency of some of the very plants on which the government is depending for its war needs. It is progressively more difficult to persuade the plant manager to light his works properly for the purposes of their use because of the noisy flurry raised by the Fuel Administration. Of course, one cannot suppose that such an unfortunate result was intended.

Mr. Powell's investigations bring to light a condition which must be remedied. In point of fact in a vast number of industrial establishments engaged on government work, where improvement in the lighting installation would not only actually save coal but considerably increase the efficiency of the workmen, and where, as in one of the instances cited here, the lighting cost is a minute proportion of the labor cost, a very small increase in the efficiency of labor would justify a considerable proportionate increase in the amount actually spent for electrical energy. The vital matter is to install lighting enough to bring the efficiency of production to a maximum and to produce this lighting at as small an expenditure of energy as the required result permits. Modern lamps in proper shades, installed in clean and bright surroundings, give illumination at a surprisingly small cost. Electrical energy is in fact about the cheapest of our necessities,

and the only one of which the cost has not risen outrageously. To curtail its use beyond the point which permits of the most efficient work is bad economy from every point of view, and particularly bad when the product is one of which the government is in dire need. It might save a few tons of coal to dispense with artificial lighting in shipbuilding plants, but the petty economy would not go far toward replacing the tonnage sunk by the U-boats.

We are not putting in a brief for the lighting companies, but we are asking in the name of common sense and sound patriotism that a check be put on the silly camouflage now altogether too common, and that every effort be made to drive directly at that larger conservation which produces big results instead of pitifully small ones.

Improving Synchronous-Motor Starting Qualities

THE synchronous motor possesses, as is well known, a great advantage over the induction motor in that it can be operated at a high power factor at any load, whereas the ordinary induction motor is characterized by a relatively low power factor, particularly at light loads. On the other hand, the synchronous motor, operated within the range of rated-load current strength, has a relatively feeble starting torque and prefers to start without load, whereas the induction motor has an excellent starting torque.

Various plans have been either adopted or proposed for modifying the synchronous motor so as to incorporate in it the advantageous qualities of induction motors. For example, copper grids, resembling portions of a squirrel-cage winding, have been applied to the stator pole faces of a synchronous motor, with the object of suppressing oscillations in angular velocity and also of increasing the starting torque.

Prof. Theo. Schou presents an article on the subject this week in which he suggests various changes in design for improving the starting qualities of synchronous motors. Among them it is proposed to utilize skin effect in squirrel-cage conductors. As a rule, the extra resistance in a conductor due to non-uniform distribution of alternating-current density over the cross-section is a pure detriment, calling for minimization and obviation. The higher the frequency of alternation, the greater the skin effect and the greater the extra resistance in the conductor due to skin effect. At starting the frequency in the squirrel-cage conductors is line frequency. At synchronism it becomes vanishingly small. In order that a strong starting torque may be combined with a strong synchronizing torque in a squirrel cage it is desirable that the resistance of the squirrel cage should be relatively large at standstill and relatively small at synchronism. This is just the condition that tends to be produced automatically by skin effect in the squirrel-cage conductors, if they are of such dimensions as to make the skin effect prominent. This property of skin effect in aiding the torque qualities of squirrel cages applies not only to synchronous motors, but also to induction motors. Consequently even so objectionable a property as the skin effect in alternating-current conductors is capable of being utilized under certain conditions. One is thus reminded that it is an ill wind which blows nobody good.

Industrial Load Relation to System Load Curve

IN THESE days when central stations are so actively engaged in ministering to the needs of industrial plants the character of their various load curves becomes a very important item in reckoning with the electrical supply problem. J. E. Mellett's paper in the current issue is particularly instructive as summarizing the actual results obtained from a large number of industries, many of them gathered from a group large enough to give something like a fair average for the particular work involved. The Georgia Railway & Power Company covers a large territory, and its experience may be regarded as rather typical.

Looking over the charts which represent the experience obtained, one is immediately struck by the necessary element of uniformity introduced by the customary hours of labor. Integration of the load from all these industries over the period from 8 in the morning to 6 at night would show a remarkably steady load factor over this period. Calls for more energy during the night come from comparatively few of the works served. Refrigeration in its various forms shows about the only case of increasing night load, although a few other industries work on a twenty-four-hour basis and consequently have about the same demands day in and day out. From the standpoint of load factor the addition of a twenty-four-hour load raises the day maximum about as much as it raises the night maximum, taking industrial plants as a whole.

Of course, the lighting load is intrinsically a night load, and it would be very interesting to know what this particular network is doing in the way of lighting load toward building up its all-day output into something like uniformity. So little work is done at night which is not also continued through the day that lighting, and particularly public lighting, becomes almost the sole outlet for energy during half the hours of the twenty-four. Taking the whole service as it comes, there is the usual heavy drop during the noon hour, a seasonal drop in the late afternoon, and a minimum between dawn and the time at which the industrial work starts up. These hollows in the load curve one cannot reasonably hope to fill.

The effect of the daylight saving program upon the situation cannot be neglected. It will undoubtedly decrease the minimum in the early evening and tend to raise the minimum in the early morning, particularly since the present regulations carry through the month of October. But until some one discovers industries which can with great advantage be pushed hard during the night the present inequalities will continue.

Some efforts have here and there been made to stimulate night consumption of energy by lowered rates, as yet without any considerable result. It is possible that certain work in which very cheap power is demanded, as in some electrochemical industries, may be able to furnish this greatly to be desired load. It is quite conceivable that certain processes which normally are carried on continuously could take advantage of a lowered night power rate to lessen the average cost of energy by pushing the production during the ordinary hours of darkness. Meanwhile our readers will find much of value in the experiences which Mr. Mellett relates.

Pushing the Output of Turbo-Generators

INABILITY to obtain generating equipment to care for increasing loads, not to mention the ever-soaring price of the equipment itself, lends new interest to the possibility of increasing the output of existing apparatus through purely mechanical means, notably ventilation. On this point we published in the issue of March 16 a very timely contribution from L. H. Parker and J. J. Preble, which gave a lively idea of the dependence of generator output on the conditions of ventilation.

With the immense output now frequently obtained from single units has come a very large amount of energy generated per cubic foot in the turbine room, and since the output in modern machines finds its limitation in heating, the difficulty of keeping a plant and its contents cool has rapidly increased. Efficient as these big units are, the loss of energy quantitatively converted into heat is astonishingly big in the total, and provisions for disposing of the heat and keeping the operating temperature of the machine down to safe limits have to be on a correspondingly liberal scale. For example, a 20,000-kva. turbo-generator requires under ordinary practice for its necessary ventilation the passage of about two and a half tons of air per minute. Were clean and cool air steadily available the necessary cooling, despite the large amount of air to be dealt with, would be relatively simple. It is an unpleasant fact, however, that air carries dirt with it, and it is estimated that under the conditions just cited the air will ordinarily carry something like one one-hundred-millionth part of its volume of dirt, which would figure up to nearly a cubic foot of dirt per day passing through, and in part lodged in, the machine.

The ventilating air passages in a turbo-generator are necessarily somewhat contracted, and when coated with dirt the effect is not only to lessen the air supply but to lessen its effectiveness by putting a non-conducting covering over the hot surface. Messrs. Parker and Preble, therefore, very reasonably put in a plea for proper cleaning of the air used for ventilation, both to help the efficiency of the process and to avoid the necessity of elaborate cleaning at not very infrequent periods. In addition, they lay considerable stress on the desirability of cooling the air artificially as part of the process of cleaning and conditioning it, so that its effectiveness in carrying off heat for the machine will be duly increased. If the ventilating air could be kept down to a winter temperature, 40 deg. to 50 deg. Fahr., the output of the machine for a fixed heating limit could be increased something like 20 per cent. Air washing accomplished thoroughly by spray or similar

means actually does cool the air by not inconsiderable amounts, varying with the temperature and degree of saturation of the air treated. Using spray treatment to clean the air, our contributors show that a cooling effect of roughly something like 10 deg. Fahr. is easily obtained, particularly in hot weather, when it is needed most. From these data they figure that the average increase in output capacity due to the use of clean and cooled air will amount under ordinary circumstances to at least 5 per cent, and on this basis they show that such treatment of the entering air is a paying proposition. The fact that several hundred stations are already equipped in this way is sufficient evidence that the importance of the matter is being practically appreciated.

Work of Outdoor Substations

WE PRESENT in the current issue an instructive little account of a California outdoor substation by L. J. Moore which is worth a careful reading on account of the simplicity of the equipment. It gives a very good notion of the line along which substation design is now drifting. The plant considered is for a 66,000-volt transmission, lowering the tension to 11,000 for distribution circuits. The construction is a little out of the ordinary in the use of wood poles with suspension-type insulators. The high price of steel on the Pacific Coast and the ease with which first-class wooden poles are obtained make the use of the latter rather attractive, particularly as the company operating the substation already maintains an open-tank creosoting plant for treating its poles. High-tension switches, both oil and air-break, are used in the 66,000-volt lines connecting with the bus at the same voltage which loops around the substation. The spacing employed is rather greater than usual, 7 ft. (2.1 m.), to lessen the danger of arcs, and the transformer bank is likewise connected to the high-voltage bus through air-break and oil switches of the outdoor type.

A variation of the usual practice is introduced in the construction of a small corrugated-iron substation house for the 11,000-volt oil switches which handle the seven feeders and for the metering equipment. It was found that for this amount and class of apparatus the difference in cost between the outdoor and indoor types was sufficient to cover the cost of the house, which also provided shelter for the station operator in bad weather. The course thus followed was probably a wise one, since it is much easier to make the smaller apparatus for indoor use.

THE application of incandescent lamps to purposes hitherto served by carbon arc lamps has been considerably extended by the development of gas-filled incandescent lamps. Until recently, however, it was thought that incandescent lamps would never entirely replace arc lamps for projection lighting. In an early issue of the *ELECTRICAL WORLD* an article will be presented pointing out how the obstacles have been overcome. Since the safety of considerable apparatus and the reliability of

The Coming Issues

service depend so directly on the proper action of transformer fuses, an article which will be presented soon on methods of assuring satisfactory results therefrom should be of interest to most of our readers. Among other subjects which will be discussed in coming issues are results of tests to determine the advisability of grounding series lighting circuits, advantages of flywheels with certain wood-working machine drives, standardization of distribution construction, and rate determination.

The Buying Line OVER HERE Helps the Firing Line OVER THERE

Lighting Curtailment in the Industries

Situation Is Serious, and Wide Publicity Must Be Given to the Truth that Adequate Lighting Is Absolutely Essential to Safety of Factory Workers and to Maximum Production

BY A. L. POWELL

THE question of coal conservation is most timely and is receiving consideration by the entire engineering profession. Preston S. Millar has recently discussed its relation to electric lighting in a paper before the Illuminating Engineering Society. A portion of this excellent presentation was devoted to industrial lighting, but this subject is of such importance that it warrants further expansion.

As the result of an extended, well-applied propaganda on the part of the Illuminating Engineering Society and manufacturers of lamps and lighting equipment, the managers of industrial plants have begun to realize the importance of correct lighting. Industrial lighting codes have been adopted by some states and are under consideration in a number of others.

WRONG IMPRESSIONS HARD TO OVERCOME

The nature of the writer's work leads him to call on many manufacturing establishments. A few months ago it was not extremely difficult to convince the shop superintendent that good lighting is an asset rather than an unavoidable expense. Since wide publicity has been given to the apparent necessity for curtailment of lighting a very different attitude is encountered. Now when one is making a recommendation covering the adequate lighting of a plant he has an initial incorrect impression to overcome. If he argues that the saving in reality is ridiculously small, he seems unpatriotic in view of the warnings sent out by the Fuel Administration and others.

The situation is far more serious than it seems on the surface, and wide publicity must be given to the truth of the matter. The writer recently inspected a shop which was formerly illuminated excellently by medium-sized efficient lamps with well-designed reflectors. To his amazement these lamps had been removed, a considerable amount of additional wiring installed, and bare, inefficient lamps hung directly in the line of view over each machine. On inquiry the writer was informed that the management was very patriotic and desired to do everything to help the government in its emergency. The plant electrician had a false impression that it was essential to hang the lamps near the work and had removed the reflectors because, as he stated, "they absorbed light!"

There are a number of reasons why we need better lighting in industrial plants.

First—It is recognized universally that there is a demand for maximum production of a thousand and one articles essential in the war. Lighting does have an effect on output. This fact has been generally recognized for a long while, yet we have never before had figures to prove it. With much interest we read in Mr. Millar's paper:

Recent tests made in a machine shop of one of the large Chicago concerns under the direction of the lighting committee of the Commonwealth Edison Company showed from

8 to 27 per cent increase in production when the lighting intensity was increased from 4 to 12 foot-candles. These figures cover eight different operations which averaged a 15 per cent increase. For each intensity a carefully designed system with deep-bowl steel reflectors was used, and every precaution was taken to insure fair results.

Second—Adequate lighting reduces spoilage. Spoilage has a multiple effect on coal consumption:

(a) The coal used to heat that part of the plant where the particular article was made has been wasted.

(b) Most products are not made completely from raw materials; therefore the energy expended on the parts of the spoiled article before it reached the shop where it was damaged is also of no value.

(c) The coal used to transport the raw material and partially manufactured goods is a dead loss.

Third—Proper lighting reduces accidents. Absolute data are to be found in technical literature on this question. It is no mere theory. Skilled labor is at a premium, and the situation will be even worse in the future. An injured man is a loss to the community. When an accident occurs in a shop not only is the production of the injured individual lost but the demoralizing effect on the other operators materially slows up production.

MAXIMUM ILLUMINATION WITH MINIMUM ENERGY

We are therefore confronted with two facts: Proper and adequate lighting *must* be supplied, and coal *must* be conserved. What must be done to get the maximum illumination with minimum energy expenditure?

Efficient lamps must of necessity be employed. We have three conditions: (a) Insufficient light with inefficient lamps in use; (b) adequate illumination but inefficient lamps supplying this; (c) efficient lamps used but inadequate illumination provided.

(a) The substitution of efficient lamps giving from three to six times the light for the same power consumption easily solves this condition.

(b) Suppose we have a shop where sufficient light is now being obtained on the work, using carbon or "gem" lamps. In order to produce the same amount of light with "mazda" lamps as with carbon lamps, a 25-watt "mazda" lamp could be substituted for each 60-watt carbon lamp, with a saving of 35 watts. Although there is a difference in price of lamps, this is much more than offset by the great power saving. A rough calculation, using list prices on lamps and power at 5 cents per kilowatt-hour, shows a net saving of \$1.55 per socket per 1000 hours. The coal saving would be that required to produce 35 kw.-hr. When one multiplies this by the number of sockets in a plant some really effective results are shown.

Even greater savings may be made where general illumination is used, for in the case of a carbon installation the lamps are usually grouped in clusters of from four to six lamps in a flat reflector. A much more

efficient unit consists of one medium-size "mazda C" lamp and proper reflector. One 100-watt "mazda C" lamp in a well-designed reflector will give more light and distribute it much better than six 60-watt carbon lamps in an old-style fixture. Figuring on the same basis as above, there is a saving of over \$13 per 1000 hours (68 per cent) for each outlet. In addition to this monetary saving there is the saving of coal to produce 260 kw.-hr. per outlet per 1000 hours' burning.

The writer has just returned from a trip to a medium-sized plant in the Middle West. At these works a total of 1200 60-watt carbon lamps were in use. There was absolutely no reason why 25-watt "mazda" lamps could not be substituted for these. In this plant it was estimated that every lamp burned on an average fifteen hours per day 365 days per year. Simple calculations reveal that in this case alone 230,000 kw.-hr. per year could be saved by the substitution of efficient lamps. Figuring on a basis of 3 lb. of coal per kilowatt-hour, this means a saving of 345 tons of coal.

Any one who stops to analyze the matter cannot understand why carbon lamps are still used in industrial plants. Even if there were a difference in strength in favor of the carbon lamp, the great difference in efficiency and resultant saving in power (35 watts) will pay for the increased first cost of the "mazda" lamp. To make up the difference in cost the "mazda" lamp has only to live the following hours:

At 1 cent per kilowatt-hour.....	350 hours
At 2 cents per kilowatt-hour.....	175 hours
At 3 cents per kilowatt-hour.....	117 hours
At 5 cents per kilowatt-hour.....	70 hours
At 10 cents per kilowatt-hour.....	35 hours

(c) Efficient lamps are used, but there is not sufficient light to carry on the work effectively. It is obvious that we can make no material saving in power or coal, but there is no doubt that one is justified in increasing the power consumption to gain increased output.

Suppose each workman has a 25-watt "mazda" lamp as a local light over each machine. This is probably the minimum that could be supplied. Experience indicates that exceptionally good general illumination can be obtained if one 100-watt "mazda C" lamp in suitable reflector is provided for each workman. This does not mean that one of these units is placed in front of or above each individual operator, but represents the average covering the entire shop. At 5 cents per kilowatt-hour there would be an increased total operating cost of roughly 0.5 cent per hour. The skilled workman in the machine shop receives at least 50 cents per hour, hence the difference in cost between inefficient lighting and very excellent illumination is less than 1 per cent of the wage expense.

Efficient lamps being in use, they should be equipped with proper reflectors to direct the light effectively to the work. Every one familiar with the subject realizes that the distribution of light from a bare lamp is not suitable for effectively illuminating a workbench or machine. Practically half the light is in the upper hemisphere and must be reflected from the ceiling before it reaches the workbench. Although a regrettable condition, it must be admitted that in many industrial plants the side walls and ceilings are not good reflectors.

Suppose a factory of 40,000 sq. ft. was to be lighted with medium-sized "mazda C" lamps to an average intensity of 3 foot-candles; walls and ceilings are moderately light in color. Using generally accepted constants, it is seen that if lamps were used without reflectors 26 kw. would be required. If efficient, well-designed industrial reflectors were used, 15 kw. would give the desired intensity of illumination—nearly a two to one ratio.

Efficient lamps being in use, equipped with suitable reflectors, what is the next step in coal conservation? Paint the upper part of the walls and the ceiling a white with high reflective power. The writer had always appreciated that this factor was important, but recently conducted a test which indelibly stamped the effect of this on his mind. Illumination readings were taken in a new factory building before the machinery was installed. Walls and ceiling were painted a special matte white with an unusually high coefficient of reflection. The floor was of light-colored wood. More lumens were effective on a 30-in. (76.2-cm.) plane than were generated by the lamps. When the problem is carefully analyzed it is seen that an effect similar to that which occurs in the Ulbrich sphere is produced, and multiple reflections give the paradoxical result.

Not only do white walls and ceilings help out the artificial lighting by actually increasing the intensity, giving better diffusion to the illumination and making the lighting more uniform, but they also benefit the natural illumination.

IMPORTANCE OF CAREFUL MAINTENANCE

When due consideration has been given to all these factors what further can be done to keep the lighting system at its maximum efficiency? Maintain it carefully. After lamps have been burned a considerable length of time they become blackened and reach a certain critical point where it is good economy to remove them, even though they will still burn. Dust, oil and dirt of all sorts accumulate on the lamp bulb and reflecting surfaces. It is most important to have a well-supervised, carefully planned system of cleaning lamps and reflectors. Under fairly clean conditions the illumination from an installation of dome-shaped enameled steel reflectors, the least susceptible of all equipment, will depreciate at least 10 per cent in a period of twelve weeks. In many cases the depreciation is far greater than this.

In conclusion, it may be well to mention one point which is only indirectly connected with the question of artificial lighting; that is, the cleaning of windows. If the maximum light is admitted from out-of-doors at all times, then the hour for turning on artificial lights is delayed. One does not fully realize the effect of dirty windows. To obtain some definite figures on this question the writer recently made a rough test. The windows in a certain factory office had not been cleaned for a considerable period of time. One pane was carefully cleaned. Photometric tests of this and adjacent dirty panes showed absorption values as high as 50 per cent. This free light was being wasted.

Give your industrial lighting problem careful consideration; save where possible; make every bit of power or pound of coal do its maximum work; but do not stint at those places where the effectiveness of your organization will be reduced.

What Substitution of Oil for Coal Can Do

Account of Some Actual Experiences in New England, Where Use of Fuel Oil Has Increased Economy, Reduced Operating Expense and Attendance Necessary, and Afforded Other Benefits

PLANTS in New England with a combined rating of nearly 100,000 hp. are to-day operating on fuel oil or have lately contracted for equipment which will do away with the use of coal in these installations. This movement toward accepting standards of fuel engineering practice long successful on the Pacific Coast began before the present coal shortage hit New England. It was accelerated, of course, by the scarcity of coal, but there is every indication that it will become a permanent development. Most of the installations are in industrial plants, but they are indicative of what can be done in central stations of a similar size or perhaps even larger.

Owing largely to the lack of normal shipping facilities by water carriers, the supply of fuel oil at present available is insufficient for development on a scale to be expected in times of peace, but even under the handicap of war conditions the growth of fuel-oil service in New England during the past two or three years has been remarkable. Aside from its use in steam-power plants, it is rapidly coming into favor as a fuel for heating boilers in office buildings, libraries, large stores and similar structures. This should be of particular interest in central-station companies which have been considering the best methods of providing heating service where an isolated electric plant is displaced.

The oil now being distributed in New England for

of coal. Expressed in gallons, 150 gal. (567.8 l.) of oil is the equivalent of about one ton of coal. Fuel oil, as used in New England, is known as crude oil in some circles. In reality it is a residuum from which the gasoline, benzine, kerosene and other light products have been removed. It does not emit an inflammable vapor below 150 deg. Fahr. and is therefore an unusually safe fuel for handling in the boiler room. It burns clean under proper operating conditions, insuring smokeless combustion, and can be handled so easily that a large shoe-manufacturing plant in Boston is planning to operate its boiler plant by women. The ease of control, speed of application and adaptability to changing load conditions attendant with oil burning are virtually revolutionizing fireroom practice in many former coal-burning plants. The absence of standby losses inseparable from the use of coal is perhaps the chief source of economy in the use of fuel oil.

Providence, R. I., and Boston, Mass., are the two principal oil ports of New England. Oil is distributed from these cities by automobile trucks and by tank cars serving boiler plants in the city districts and the interior. The price per gallon has varied from 2.5 cents in 1915 to a maximum of 6 or 7 cents, a fair present average being from 4 to 5 cents. The automobile trucks used in this service carry about 1500 gal. (5678 l.) each and can be emptied by gravity in six minutes. In the Provi-

FIGS. 1 AND 2—COAL HAD TO BE PILED IN FRONT OF THE BOILERS AND MORE FIREMEN WERE REQUIRED BEFORE FUEL-OIL BURNERS WERE INSTALLED

steam plant service is largely the so-called "topped" oil from Mexican or other southern wells and has a heating value of from 18,300 B.t.u. to 18,500 B.t.u. per pound (10,100 cal. to 10,250 cal. per kg.). About 1600 lb. (725.7 kg.) of oil furnishes the heating equivalent of one ton of New River coal, or about 4.5 barrels of oil per ton

dence district one truck delivers ten or twelve loads per day, or the heating equivalent of 100 tons of coal. There is no question that a continuous supply can be relied upon despite the distance of New England from the oil fields.

Many advantages attend the use of fuel oil. Higher

efficiency at the boiler results, owing to more perfect combustion with less excess air and, accordingly, less heat lost up the stack. A more equal distribution of heat in the combustion chamber is secured, as the fire doors do not have to be opened, and more heat is absorbed because of the clean condition of the tubes. As no cleaning of fires is required, boilers can be operated at their maximum capacity continually if necessary. There is a reduction in the cost of handling fuel, as this is done mechanically or by gravity. No expensive conveying or elevating systems are necessary, as fuel oil is delivered either by pumping or by running under gravity into storage tanks. This means economy in first cost of a plant designed new, as well as in handling fuel.

No firing tools or grate bars are necessary; but if the supply of oil should be threatened, which is unlikely, the withdrawal of the burner equipment and installation of

ing any productive work. In a representative New England power plant two 500-hp. boilers were carried banked for two months, ready to be cut in on the line at a moment's notice; but as the demand for a sudden increase in output did not arise all the coal used in this way was wasted. The cost of banking these boilers was \$300 a week.

With fuel oil only one fireman is required to handle ten to fifteen boilers. In a New England station equipped with fifteen Babcock & Wilcox boilers, aggregating 5500 hp., and operating three eight-hour shifts daily, sixty-three men were employed in the fireroom when burning coal. After the plant was converted to oil only seven firemen were required. Depending on the grade of coal used and the draft conditions, from 10 to 75 per cent increase in boiler capacity can be obtained in many cases by using fuel oil. As the stack area re-

FIGS. 3 AND 4—THE UNTIDY BOILER ROOM, WITH ITS DIRTY FLOORS AND ASH CANS WHICH HAD TO BE EMPTIED, WAS AVOIDED BY BURNING FUEL OIL.

grate bars in the boiler furnace is a simple matter. Increased life of furnace linings and brickwork follows the use of oil, and damage to the brickwork from tools used in removing clinkers is eliminated. The absence of coal dust, dirt and ashes enables the boiler room to be kept clean, reducing the wear on pumps and other machinery, while the cost of handling and removing ashes is also entirely eliminated.

In New England plants, as elsewhere, the use of fuel oil enables the engineer to leave his boilers without any fire under them to within a short time before they have to be cut in on the line. The burners are then lighted, and in a few moments full working pressure is attained. Fluctuation in boiler loads can be handled on a moment's notice by turning the supply valve equipment, and this can be and is made automatic in many installations. As soon as the demand ceases the fire can at once be turned down to normal or extinguished entirely, as the occasion requires. This represents a large saving in plants which are operated only twelve hours per day and carry their fires banked the rest of the time.

On a 200-hp. return-tubular boiler about 3000 lb. (1360.8 kg.) of coal is used weekly for banking fires at night and making new fires in the morning without do-

quired for oil burning is only 50 per cent of that needed for coal, 40 per cent more power can be developed from the same chimney. The increased attention given to smoke laws by public authorities has made the production of smoke in city plants a serious question. In a properly handled oil-burning station smoke is eliminated entirely, except in a few cases where the stack will smoke for a short time while the burners are being started.

Tests were recently conducted on two 140-hp. horizontal-return tubular boilers in regular service, operated under the usual plant conditions, with coal firing and when burning fuel oil. Each test covered a period of one week, starting with cold boilers Monday morning and continuing until Saturday noon, when the mill closed down. A summary of the test is printed on page 713.

Using coal, one head fireman, two day firemen, two night firemen and one ash handler were required. With oil only one head fireman and one night fireman are needed. To the fireroom labor cost, with coal, must be added the cost of one team and one man working six days per week hauling coal from the pocket to the fire room, about 200 yd. (182.9 m.), and also the cost of

handling and disposing of ashes. Fuel oil has eliminated this handling. Deliveries are made by tank car to the mill siding, and the oil flows by gravity into three steel storage tanks holding 587 barrels each. From this storage the oil is drawn by a duplex service pump set on the boiler-room floor and is discharged by these pumps through a circulating-pipe system to the boilers, which are equipped with the Hammel oil-burner system.

Normally the mill closes down at 5.30 p. m. When coal was the fuel it was the practice to bank the entire in-

stallation of twelve boilers for the night. Consequently the standby losses were high. With fuel oil the fires under all but one or two boilers are turned out and the boilers closed. It is noteworthy that when the fires are lighted the next morning the steam pressure has dropped only about 12 lb., and only about five minutes are required to bring the boilers back to full working pressure.

Another notable plant which is operating on fuel oil is that of the Jenckes Spinning Company, Pawtucket, R. I., which has an installation of 1700 boiler-hp. At the end of eighteen months' service a statement was issued by George Fish, mill manager, to the effect that the company had found the oil system much easier and cheaper to use, with a saving in maintenance over coal. The steam capacity was increased from 40 to 70 per cent over the boiler rating, which saved the company an expenditure of at least \$15,000 on new boiler equipment which would have been required if it had continued to use coal. Fuel oil permitted a saving of \$2,100 per year in labor, \$600 on ashes removal and about \$6,000 on fuel under normal conditions. This record led to the equipment of the affiliated Tamarack Company's No. 2 mill power plant with oil. This station is one of the largest oil-burning electric power plants in New England. At present it contains a 2500-kw. General Electric turbine delivering three-phase energy at 550 volts for miscellaneous power service in the establishment. In a test made at the first Jenckes plant with coal and fuel oil relative efficiencies of boilers of 66.6 and 81.5 per cent were obtained, with evaporation of 10.02 lb. (4.5 kg.) of water from and at 212 deg. when burning coal and 15.21 lb. (6.9 kg.) with oil.

Since the middle of August, 1915, eighty-nine installations have been made in New England of the Fess system of oil burning, both rotary and fixed burner outfits being in service. In this system, where the rotary burner is used, the fuel oil is forced into a turbine burner

and discharged in atomized form into the furnace, the pressure being furnished by a rotary pump in the supply pipe line, both pump and burner head being driven by a constant-speed electric motor. In practice the motor usually requires from 1/8 hp. to 3/4 hp. according to conditions. The standard speed is 1750 r.p.m., and the burner head revolves at 3500 r.p.m. Many of these outfits are in service in institutional boiler plants, office buildings, newspaper plants, and similar places. A number of small isolated power plants are also using fuel oil, and the advantages outlined above in connection with industrial power plant service from oil apply equally to buildings of considerable size. The saving of labor effected by eliminating stand-by losses is accompanied by the fuel economy resulting from the same cause. Boiler rooms have been transformed from dingy, unclean places to places which are as clean as the modern turbine room. Furthermore, the flexibility of control and automatic features of fuel-oil service have proved very valuable. Automatic control of the inflow of oil can be effected by the connection of the damper regulator with the supply valve, enabling the plants to be left alone sometimes for hours.

At the plant of the Almy Water Tube Boiler Works, in Providence, illustrated herewith, a 45-hp. boiler of the company's make is equipped with a Fess fuel-oil burner of the rotary type. This is driven by a 1/2-hp., 550-volt Holtzer-Cabot induction motor and is equipped with the usual damper regulator control of the oil valves. In two years' operation the use of oil has saved the company from 18 to 23 per cent on the basis of coal at \$4.50 per ton. This boiler delivers steam within ten

FIG. 5—FUEL-OIL BURNERS APPLIED TO OLD COAL-BURNING BOILERS

minutes of starting at 200 lb. pressure, and the automatic regulation holds the pressure constant within a pound through wide fluctuations of load. The evaporation is from 12 lb. to 14 lb. of water per pound of oil.

The block plant known as the Lauderdale plant in Providence is now being fully equipped for fuel-oil service. In this case there are four 125-hp. Babcock & Wilcox boilers equipped with stationary burners. Atomization is by steam jet; an 8000-gal. tank stores the necessary fuel and a duplex pump of the steam-driven

type forces the oil into the furnace. An automatic regulator is provided, operating on a balance between the steam and the oil pressure, to control the oil supply to the furnaces. At present from 1200 gal. to 1700 gal. (about 5500 l.) of oil per day is burned with two boilers equipped. Eight buildings are supplied with steam, water or electric service from this plant, which has a generator rating of about 190 kw. The load in this plant varies during twenty-four hours from 20 kw. to 500 kw., yet the automatic control of the steam pressure through the governing of the oil supply is so close that practically no change is observed in the steam pressure.

It is customary to install rotary burners for plants up to 100 hp. to 125 hp. per boiler; above these ratings the fixed type of burner with steam-jet atomization is generally required. The average oil pressure in rotary

burner plants is about 15 lb. per sq. in. (1.06 kg. per sq. cm.). No pressure is carried on the tanks in such plants. The oil is warmed by steam or hot-water coils surrounding the main supply line from the tank to the pumping outfit, and a by-pass pipe to the tank provides for the convenient return of unused or unrequired oil from the pumping set and related piping. In the large fuel-oil plants installed for industrial power service the oil is warmed by steam coils in the storage tank itself.

Careful study of the supply conditions indicates that there is no ground for serious apprehension as to the situation which may be expected when the world war becomes a matter of history. Meanwhile a steady development of fuel oil in the boiler plant is likely to be witnessed, its magnitude depending upon the possibility of increasing the present supply of this most valuable source of heat energy.

Improving Synchronous-Motor Starting Features

Lines Along Which Improvements Can Be Made in the Design of These Motors, with a Brief Record of the Results That Were Derived from Some Investigations Made Concerning the Effectiveness of the Methods Employed

BY THEO. SCHOU

Assistant Professor of Electrical Engineering, State University of Iowa

WHILE valuable improvements that widen their field of application have been made in synchronous motors, the self-starting feature has not been developed as far as it could be. Probably the reason is that designers and manufacturers desire to use the same patterns, tools and dies for both generators and motors and hence cannot incorporate features in the motors which would give them better characteristics as such. In what follows the author proposes some changes or slight modifications that should give synchronous motors better starting and operating characteristics and then goes on to explain some experiments which were conducted to test the effectiveness of

chronous type. The slip that is inherent with the induction motors is, of course, eliminated in the case of synchronous motors. It is, therefore, possible to design a synchronous motor that has starting characteristics (*i. e.*, ratio of starting torque to kva. input) as good as or even better than a similarly rated induction motor. If, however, a synchronous motor is called upon to pull into synchronism with a heavy load, then the design of the squirrel-cage winding must be modified at the expense of starting torque, so as to enable the synchronous motor to run as an induction motor with a small enough slip to effect pull-in with the respective load.

FIG. 1—PULLING-IN CHARACTERISTICS OF A SYNCHRONOUS MOTOR WITH SELF-EXCITATION

the construction suggested. The results of this investigation are given in the form of oscillograms and plotted curves.

While the calculation of the squirrel-cage winding, in case of induction motors, is based on running as well as starting conditions, only starting and pull-in characteristics need be considered with motors of the syn-

As the frequency in the squirrel-cage winding changes from normal at standstill to zero at synchronous speed, it is suggested that advantage be taken of materials having pronounced skin effect in designing squirrel-cage windings for synchronous motors. In this manner high resistance with large torque at starting and low resistance with small slip at pull-in, which

ould be very desirable, can be obtained. A synchro-
us motor can be made to pull in full load or more if
e applied voltage is high enough. The objection to
roviding over-potential taps on the auto-transformer
the large current which the motor would draw from
e line at pull-in. This condition, however, can be
mewhat improved by using auxiliary reactance, thus

rent is applied to its terminals, has less reluctance the
smaller the air gap between the stator and the rotor.
Therefore the magnetizing current which a motor draws
from the line to establish a certain flux is smaller the
less the air gap, other conditions remaining unchanged.
Furthermore, the slots in the stator and rotor increase
the reluctance of the rotating field, more or less, de-

FIG. 2—PULLING-IN CHARACTERISTICS OF SYNCHRONOUS MOTORS WITH SEPARATE EXCITATION

olonging the time-factor element and reducing the
urrent during the pull-in period.

Different pull in characteristics are obtained, de-
ending on the method of excitation used as shown by
gs. 1 and 2. The oscillograms refer to a 62½-hp.,
00-volt, two-phase, 60-cycle, 720-r.p.m. synchronous
otor that was designed by the writer for research
rposes. This motor is equipped for both separate
ecitation and self-excitation. The pull-in characteris-
cs were taken under exactly the same conditions—
e., same load to pull-in, same slip at pull-in and same
plied voltage. On applying separate excitation the
ll-in current is very large and excessive when the
ld circuit is closed. With self-excitation, however,
e current is not excessive and decreases gradually.

Tests on this motor also suggest that when self-
cited the motor will pull into step a larger load

pending on their shape and size, or tend to increase the
magnetizing current drawn from the line. The effect
of the stator and rotor slots is, therefore, to increase
the air-gap of the motor, electrically speaking.

Since synchronous motors are almost exclusively of
the definite pole type, the air space between poles is
equivalent to large rotor slots. The larger this air
space or the smaller the relative pole span* the
larger the magnetizing current must necessarily be.
In the case of an induction motor the air gap proper is
uniform around the entire machine. With the syn-
chronous motor the poles are more or less tapered in
order to establish a desirable flux distribution curve.
In a synchronous motor, therefore, the air gap meas-
ured at the center of the pole is smaller than that meas-
ured at the pole tips; that is, designers have to con-
sider the average air gap and then increase it enough to

FIGS. 3, 4 AND 5—SOME ROTORS IN WHICH SQUIRREL-CAGE WINDINGS HAVE BEEN EMBEDDED TO IMPROVE STARTING CHARACTERISTICS

an would be possible with separate excitation. Nor
it so sensitive to flywheel effect as the present type.
An ordinary alternator cannot be made to develop
ood self-starting, synchronous-motor characteristics
merely adding a squirrel-cage winding, for the fol-
owing reasons: The rotating field, as established in the
mature of any polyphase motor when alternating cur-

compensate for the effect of the stator and rotor slots.

With alternators the length of air gaps is electrically
limited, because with a given rating the field strength
must be able to produce practical regulation character-
istics. Furthermore, the relative pole span* is limited

*Ratio of pole arc to pole pitch.

in order to prevent excessive field leakage, which would lower the ability of the generator to maintain voltage at low lagging power factors. For the same reason it is also desirable to design the poles with shallow and well-tapered pole tips.

With induction motors, on the other hand, it is de-

pull-in characteristics are only approximately correct owing to the difficulty of obtaining reliable meter readings at pull-in. Similar methods of making tests and readings being employed in both cases, the curves serve excellently as a comparison between the results which may be obtained with the modified alternator design

FIGS. 6, 7 AND 8—STARTING AND PULL-IN CHARACTERISTICS OF STANDARD ALTERNATOR AND SYNCHRONOUS MOTOR; STARTING CHARACTERISTICS OF SYNCHRONOUS MOTOR UNDER TWO CONDITIONS, AND EFFECT OF LOAD ON POWER FACTOR

The curves shown in Fig. 7 were plotted from data obtained with the field short-circuited through a resistance of approximately twice the field resistance. For equally applied voltage the following results were obtained in favor of starting with open field: Increase of starting torque, approximately 10 per cent; de-

crease of starting kva., approximately 17 per cent; decrease of amperes per terminal, approximately 17 per cent. At the 50 per cent voltage tap, however, the induced field voltage at starting was 2380 volts. This induced voltage is, of course, proportional to the applied voltage.

sirable to have the highest possible induction in the rotor, or in the secondary circuit, with an appropriate line current drawn by the stator. To attain this object the rotor is made cylindrical with no definite poles, the air gap being made as small as possible to decrease the magnetic reluctance for the stator field and thus decrease to a minimum the magnetizing current on which the wattless component depends. The air gap in the induction motor is, therefore, limited by mechanical conditions.

Correct synchronous motor design should take both of the foregoing requirements into consideration. To obtain practical and economical design the synchronous motor is almost always of the definite-pole construction, therefore the field leakage must be taken into account. It is not necessary to consider regulation characteristics with this type of motor; for this reason the equivalent air gap (air gap proper plus that due to stator and rotor slots) can be made smaller than would be the case with the corresponding alternator. This will decrease both the field leakage and the field copper loss and permit a larger pole span. As most synchronous motors are operating at approximately 100 per cent power factor, the problem of field leakage is not so serious as with standard alternators.

By increasing the pole span the active rotor material permits an effective and well-distributed squirrel-cage winding. Thus a machine is obtained that approaches the induction motor in design as well as in starting characteristics. Figs. 3, 4 and 5 show rotor designs of synchronous motors that will produce starting and pull-in characteristics like those reproduced in Fig. 1. In connection with these characteristics it should be noted that the starting characteristics are based on that position of the rotor with respect to the stator that gave the most unfavorable results. Furthermore, the

and what may be obtained if the design features previously mentioned have been applied.

It is very essential that a well-designed synchronous motor should start from any position of the rotor in relation to the stator when equal or approximately equal voltages are applied. If not well designed, a synchronous motor may show very good starting characteristics in one position of the rotor and very poor ones in another.

Contrary to the general opinion, the writer has noticed that the distribution of the armature winding and the nature of the material used in the squirrel-

FIG. 9—PULL-OUT CHARACTERISTICS OF A 400-HP., 2200-VOLT 150-R.P.M., THREE-PHASE, 60-CYCLE SYNCHRONOUS MOTOR

cage winding have more effect on the "dead points" than the air gaps or rotor and stator slot pitch. The application of part-slot windings (discussed in detail by the writer in the ELECTRICAL WORLD of March 17, and April 21, 1917) and the use of material for the squirrel-cage winding that has non-uniform resistance such as brass, will make any synchronous motor approximately "dead-point" proof.

While it is a well-known fact that synchronous motors, especially those equipped with high-resistance squirrel-cage windings, have better starting characteristics with an open field than with a short-circuited one, the gain is so slight that it is not warranted because of the dangerously high voltage that is induced in an open field winding at starting. The voltage induced in the field windings of standard machines designed for 125-volt excitation is not only liable to puncture the field insulation but it is also dangerous for the operator, because it will exist at the field switch on the switchboard. In the case of self-excited synchronous motors the fields may be wound for low voltage, say 25 volts, which would mean few turns of large wire or strap, thus eliminating any danger of high induced field voltage. Furthermore, it would permit starting with an open field,

factor of a synchronous motor with variable load and constant field excitation, it can be determined from the phase characteristics. Figs. 8a, 8b and 8c show respectively how the power factor of one synchronous motor changes with the load when the field excitation is set for approximately no load 100 per cent power factor, full load 100 per cent power factor, and 150 per cent of full load at 100 per cent power factor. If the synchronous motor is desired to operate as a power motor at approximately 100 per cent power factor, the field should be so designed in respect to the excitation voltage that no rheostat is necessary in the field circuit. This results in greater efficiency than with a motor whose field winding is of the standard alternator design allowing for operation at low leading power factors. If operation at about 100 per cent power factor is desirable, a certain amount of energy loss is involved in the field rheostat. This should be charged against the efficiency of the motor. It should also be remembered that field rheostats, especially for large low-speed motors, when not needed represent dead capital.

The limit-of-stability curve, indicated in Fig. 10, is also of interest, as it shows the critical load that might be approached with a certain field excitation. This curve may also be termed the pull-out curve. If extended far enough, it will reach a certain maximum value and then decrease with increased excitation.

The pull-out tests being taken at half-normal voltage, the curve was replotted for normal voltage, assuming that the pull-out torque increases as the square of the voltage. Under ordinary operating conditions—i.e., approximately normal voltage and frequency and fairly steady load—the pull-out with well-designed synchronous motors need not be considered. With the excitation set for approximately full load and 100 per cent power factor and approximately normal voltage and frequency applied at the motor terminals, the pull-out torque (as much as 900 per cent full-load torque) is usually far above the heating limits of the motor. If, on the other hand, the fluctuations of voltage, frequency and load are very pronounced, the application of synchronous motors may not be desirable, owing to the danger of pull-out.

The pronounced peaks reproduced in Fig. 9 are characteristic for a synchronous motor with improper flywheel effect, supplied by a large system at approximately constant frequency and connected to a stone-crushing load. If an induction motor had been employed, these peaks would not be so pronounced, because the motor would slip on instantaneous heavy overloads and allow the flywheel effect to act. Since flywheel effect only assists during a change of speed and as a synchronous motor supplied by constant frequency current slips only a fraction of a cycle, it is obvious that the problem of securing proper flywheel effect with synchronous motor drive is quite different from that encountered with induction motor drive.

The danger of pull-out due to excessive, instantaneous load might be conveniently eliminated by installing a magnetic clutch between the synchronous motor and its load. This magnetic clutch can be set to slip at any desired fixed load and thus permit the flywheel effect to act during such peaks. No doubt in the near future the advantages that will result from the application of synchronous motors under appropriate operative conditions will justify its more extensive use.

FIG. 10—LIMIT OF STABILITY AND EFFECT OF LOAD ON POWER FACTOR

with the corresponding gain in starting characteristics (see Fig. 7).

Under synchronous running conditions, with approximately constantly applied voltage, the relation of load, excitation and power factor may be very conveniently studied or computed from the phase characteristics of the motor in question. While the determination of the phase characteristics or V curves involves rather tedious and expensive tests, they can easily be constructed from the commercial test runs, using the method fully described by the writer in the ELECTRICAL WORLD of Feb. 12, 1916. The results obtained by this method check approximately with actual test results. Such curves as those reproduced in Fig. 10 are very useful and practical, as they show at a glance reliable information as to the operating characteristics of the synchronous motor at various loads and field excitations.

When it is of interest to know the change of power

Construction of Outdoor Substation at Madera, Cal.

Preference Given to Suspension Insulators and Wood Poles—Reasons Which Have Influenced the Management in Housing Some of the Equipment—Provisions Adopted for Maintaining Reliable Service

BY L. J. MOORE

Engineer San Joaquin Light & Power Corporation

THE San Joaquin Light & Power Corporation of Fresno, Cal., has an outdoor substation near Madera, in the same State, which may be of interest because of its construction and moderate cost. Suspension construction on wooden poles is employed throughout. The San Joaquin corporation has always been partial to wood poles, owing to its proximity to the Oregon and Washington supply of timber. A quite extensive open-tank creosoting plant is maintained in Fresno for the treatment of poles which are used on the system. The present high cost of steel was also a factor in determining the use of poles for this substation. Other substations which have been erected by this corporation have usually been constructed with pin-type insulators on wood poles. All future installations are to be made with suspension insulators, thus making it possible to increase the amount of insulation installed and to secure better mechanical construction than is possible on pin-type insulators. Except for the metering equipment and low-tension oil switches all the equipment in the Madera substation was placed out of doors.

The substation is connected to a 66,000-volt line which forms a loop through a number of other substations. The transformation ratio is from 66,000 volts to 11,000 volts through a Y-Y bank of transformers with both high-tension and low-tension neutrals grounded. An oil switch and an air-break switch are installed in the incoming and outgoing 66,000-volt lines where they connect with the 66,000-volt bus which loops around the substation site. A spacing of 7 ft. (2.1 m.) has been used between high-voltage wires where possible to lessen the occurrence of arcs or trouble caused by large birds flying between the wires. The transformer bank is connected with the 66,000-volt bus through an air-break switch and an oil switch. Provision is made for seven 11,000-volt feeders, two of which are carried on the transmission-line poles. All 66,000-volt air-break switches used in the station are

five-disk K-P-F switches, chosen because their construction especially fits them for use in this type of substation. A grounding switch is installed on each end of the 66,000-volt lines in order to ground either section of the line in case men have to work upon the line between this station and either one of the two stations adjacent to it. The two grounding switches are mounted on 66,000-volt pin-type insulators, which are

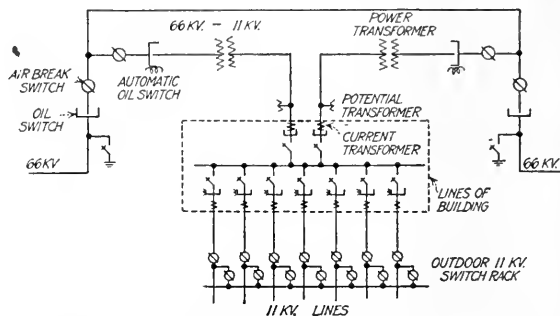

FIG. 2—ELECTRICAL WIRING LAYOUT, SHOWING CONNECTIONS

the only high-tension pin-insulators in the installation.

The transformer bus is supported on 25-ft. (7.6-m.) poles and is long enough to accommodate two banks of three 500-kva. transformers, together with one spare and the controlling switches for both banks. (See the accompanying plan). Only one bank of transformers and a spare are installed so far, however, awaiting the need for more equipment. The 66,000-volt buses are on the arms across the tops of the poles, and the 11,000-volt buses are supported in a vertical plane on the poles themselves along one side of the structure. The buses are dead-ended in the center of the structure over the spare transformer so that it may be connected in place of any transformer in either bank which might become disabled. This location was chosen for the spare unit in order to minimize delay and work in connecting it into service.

In the center of the outdoor substation site is a

FIG. 1—GENERAL VIEW OF MADERA (CAL.) OUTDOOR SUBSTATION

corrugated-iron-covered wood-frame building which houses the metering equipment and the 11,000-volt oil switches. All the equipment in the building could and would have been purchased for outdoor installation had it not been for the fact that this type of building adds no more expense than the difference in cost of outdoor and indoor type switches and metering equipment. Also, it was thought desirable to provide a building so that the operator would be near the indicating instruments and the automatic feeder switches. If no building were provided, he would in all probability spend most of his time in his home, especially in bad weather, when line trouble would be most likely to occur.

The electrical equipment in the building consists of an 11,000-volt bus to which leads from the 11,000-volt side of the station transformers connect through a 300-amp., 15,000-volt General Electric K-12 oil switch and disconnecting switches. Similar equipment is installed on each of the seven feeders which tap off from the 11,000-volt bus. The switches and buses are mounted on pipe framework throughout. The feeder switches are automatic, but the switch on the transformer leads is not automatic. The metering equipment installed consists of three single-phase watt-hour meters, three ammeters, one Bristol recording voltmeter with a seven-day chart, and an indicating voltmeter which may be connected through a potential receptacle to any one of the three phases. This equipment is connected to current and potential transformers on the 11,000-volt transformer leads and measures the output of the transformers to the station bus. No metering equipment is installed on the individual feeders. Current transformers, however, are provided in each feeder for tripping the K-12 switches on overload

former is installed in the same manner to supply lights for the station building and grounds.

A very convenient 11,000-volt switch rack and paralleling bus has been provided outside the building, and all 11,000-volt feeders pass through this rack to the outgoing lines. A No. 1417 Pacific Electric & Manufac-

FIG. 3—ARRANGEMENT OF OUTDOOR SUBSTATION EQUIPMENT AT MADERA, CAL.

turing Company air-break switch has been installed on each outgoing feeder as a line "disconnect" to permit work on the oil switch inside the building. Each feeder taps outside this air-break switch through a second air-break switch to the paralleling bus, thus making it possible to attach any number of feeders to

FIG. 4—METHOD OF CONNECTING 66-KV. TRANSFORMERS AND OIL SWITCHES WITH BUSBARS

or short circuit. Potential transformers for the metering equipment are installed on a pole outside the building, the secondary leads being brought into the building through conduit. This potential bank consists of three 1-kw., 6600-volt pole-line transformers which are connected in star for 11,000 volts with the neutral grounded. An 11,000-volt, 2½-kw. pole-line trans-

a single oil switch inside the building while repairs or adjustments are being made on the switches which are ordinarily connected with them. The long California summer causes all equipment to become very dusty if it is not cleaned often, so arrangements for taking apparatus out of service without interruption to it are very necessary in order to keep the equipment clean

enough to operate satisfactorily and without danger of insulator flash-over due to the heavy coating of dust.

The substation site covers two acres, thus giving ample room for the necessary electrical equipment and the cottage for the operator. Only one operator is employed, because very little switching is necessary, and all of the automatic switches are provided with

FIG. 5—METHOD OF CONNECTING 66-KV. OIL SWITCHES WITH OVERHEAD BUS

alarms so that in case one of them trips the operator is made aware of it. A 7-ft. (2.1-m.) woven-wire fence incloses the entire property, and a similar fence is installed around each of the 66,000-volt oil switches and any other equipment which might cause injury to any one coming in contact with it. The posts in the fence and the poles in the yard are painted a dark green. All cross-arms are painted yellow in accordance with a California state law.

The substation is provided with a private telephone connected with the corporation's private line, which is carried on the transmission line poles. Means for opening the telephone line and testing for trouble on it are provided. Connection to the operator's cottage is made

FIG. 6—TRANSFER BUS RACK FROM WHICH 11-KV. FEEDERS RADIATE

both from the private line and from the Bell system.

At the time of writing this article the details of the cost have not been compiled in full, but as far as it is possible to determine from the data on hand the cost of the substation complete, including operator's cottage, well, fences and all details, will be in the neighborhood of \$15 per kilowatt of ultimate capacity.

The substation was designed and constructed by the writer, who is engineer for the San Joaquin Light & Power Corporation under the direct supervision of E. A. Quinn, general superintendent of the corporation.

ELECTRICAL MEN IN THE THIRTY-SEVENTH ENGINEERS

Regimental Mobilization Almost Complete—Two Battalions, Six Companies and 1500 Soldiers Compose the Personnel

The Thirty-seventh United States Engineers, which has been organized for electrical-mechanical service and trained at the old officers' training camp quarters at Fort Myer, Va., just outside Washington, has practically completed its mobilization, although there are some vacancies still open for enlistment to men beyond the draft age. The officers for the regiment, who have been taken mostly from the Engineers' Reserve Corps, have all been selected, and most of them are now assisting in putting the men through military training, one company at a time being now at work on the rifle range.

The regiment, which is under command of Col. Theodore H. Dillon, U. S. A., and consists of two battalions

COLONEL T. H. DILLON AND MEMBERS OF HIS STAFF, THIRTY-SEVENTH UNITED STATES ENGINEERS

of three companies each—a total of 1500 men—will be occupied with the construction, operation and maintenance of electrical and mechanical equipment. Included in the regiment are linemen, wiremen, general electrical repairmen, armature winders, oxy-acetylene welders, chauffeurs, automobile mechanics, machinists, boiler-makers, pattern-makers, molders, plumbers, pipe-fitters, carpenters, handy-men and cooks. These are rated as privates, and the promotion from that rank is to private, first class; corporal; sergeant; sergeant, first class, and from that to the higher engineer corps ratings.

Major Arthur B. Kratz, one of the officers of the regiment, made trips around the country for recruiting purposes in gathering that regiment, and upon one occasion he obtained in Chicago alone 400 men for the regiment within five days. In addition to the assistance rendered by the Illinois State Council of Defense in recruiting, the officers of the regiment received assistance from the American Electrical Committee for France and from the N. E. L. A.

Industrial Load Characteristics

A Study of Typical Daily Load Curves, with Demand and Load-Factor Figures for a Varied List of Industries and Institutions Ranging from Laundries to Federal Prisons

BY J. E. MELLETT

Power Sales Engineer, Georgia Railway & Power Company, Atlanta, Ga.

TAKEN as a whole, the central stations at the present time are probably serving electrical energy to every type of active industry. While most of the large power companies serve industries of wide diversification and secure a resultant diversity factor, some are geographically situated in so-called specialized industrial centers with predominant industries, such as steel manufacturing, coal mining, textile manufacture, flour milling, fertilizer manufacture, etc., and operating load factors are consequently to some extent affected. It will be of interest along this line, then, to note the accompanying list of a few types of industries served from the high-tension lines of the Georgia Railway & Power Company, Atlanta, Ga. This group does not include a great variety of industries served from its underground system or overhead commercial alternating system, nor those served indirectly through the many municipalities and other public service companies purchasing service from the company. Although large blocks of power are being used by distinct groups, such as textile mills, fertilizer plants, barytes mining, municipal distributing systems and municipal pumping, the large number of diversified industries connected to the system offsets the effect of group load factors and creates a wider diversity factor.

The maximum demands, kilowatt-hours per year per kilowatt of maximum demand and load factors included in this list of industries are based on the data for one plant in each class of industry. Observations of a number of load curves covering a wide period of time show that, while the maximum kilowatt demand varies with each plant in certain classes of industries, the general characteristics of load curves and load factors show very little variation.

A case in point was demonstrated by utilizing a composite of seven fertilizer-plant load curves. Each curve followed very closely the outlines of the others for each hour of the day and the variation in monthly kilowatt-

est number of warm carcasses are prepared and delivered to storage in the early evening.

Barytes mining requires a large volume of water to wash and assist in disintegrating the ore, and the load at night, of course, depends to a large extent on how badly production is needed. The same holds true with other mining.

Normally the load curve of a cottonseed-oil mill is flat, with a high load factor covering the period of operation, which runs anywhere from four to twelve months, depending on the location of the mill and its ability to secure seed. The peak at 6 o'clock, as shown on the curve, is not characteristic but is caused by a cake mill becoming clogged. Theoretically a cotton-lint bleaching plant should have a uniformly flat load curve, but there are times when trouble is experienced in removing lint from the steam-heated caldrons. This in turn affects the delivery of lint to the dryers and cleaning machines. The final product has a very fine snow-flaky appearance. It is ground still finer and used for gunpowder. The cotton-oil refinery load is usually flat for nine or ten hours and sometimes runs as long as twenty-four, depending on the production desired. Ammonia compressors are used to congeal the hot refined cottonseed oil, which is later compressed through weighing machines and sold as vegetable compound lard.

The accompanying chart of a cotton-gin load is an exceptionally good one and is much better than the average. This business is not desirable, as the load factor is very low and the return on the capital invested per kilowatt is small.

Cotton-delinting plants operate twenty-four hours per day, and the average load conditions are much better than the illustration. Briefly the process consists of beating the lint from cottonseed hulls. These beaters are usually arranged in batteries requiring a 200-hp. motor for each battery.

FIG. 1—GRAPHIC CHART OF A BILLET-MILL LOAD

hour consumption. A typical load curve of a fertilizer plant is shown herewith.

The load curve on the abattoir plant shows a gradual rise from 10 p. m. to 11:30 p. m. This is explained to some extent by the fact that a refrigerating machine is used to keep the meat storage boxes cool. The large-

The electric oven load, as shown, is somewhat erratic owing to the fact that the oven is controlled thermostatically to maintain a certain temperature in drying car bodies sprayed with enamel paint.

Limestone crusher peaks come on when large pieces of rock are dropped from cars or incline to the large

FIG. 2—REPRESENTATIVE DAILY LOAD CURVES

The peculiar features of each class of load are here brought out in comparison with other loads and tend to show the effect of peak building and load diversity on any system. Most of the loads, of course, drop off in the evening. Certain of the loads have a very high load factor; for instance, the cottonseed mill, the

oxygen-gas generator, ice-cream manufacturing and refrigeration. Others, like the cotton gin, have a poor load factor. The similarity of the load curves in the textile industry, though for different operations—cord and twine making, hosiery yarn spinning, khaki cloth manufacture—is noticeable.

crushers. The yearly load factor depends on the outside weather conditions.

The generation of oxygen gas for welding and other purposes is a very desirable load with a high load factor.

The graphic chart for a billet mill indicates a very irregular load, which compares well with average

FIG. 3—LOAD CYCLE OF A BILLET GOING THROUGH ALL SIX PASSES

conditions. The bloom and billet mills are usually timed to promote continuous operation, but there are periods when some delay is caused at the bloom mill which in turn affects the load on the billet mill. If a new billet is not received in the first pass of the billet mill before the cold end leaves the sixth pass, it naturally follows that the load on the billet mill motor will drop off to friction load only.

Average conditions covering a number of records taken show that the demand on a 1600-hp. motor for one minute on cold steel is 1725 kw., on hot steel 1200 kw., an average load of 600 kw. and a friction load of 75 kw. doing the work as specified on the accompanying chart.

The average billet requires thirty seconds to reach the sixth pass, remains sixty seconds in the sixth pass, and the cold end requires twenty-nine seconds to leave the mill, thus consuming a total of 119 seconds for the entire number of passes. Numerous observations show a consumption of 30 kw.-hr. per completed billet. As several synchronous motor-generator sets are operated at this plant, no power-factor trouble is experienced.

The load curve as shown for a national army cantonment may be considered as typical for this class of business, especially at reveille and early evening. The valley between 8 a. m. and 5 p. m. is probably more pronounced at this camp than at others, owing to the fact that water is received from the city of Atlanta and then pumped to standpipes to secure proper fire pressure, where, on the other hand, the direct pumping load would be slightly heavier at camps isolated from a similar source of water supply. A load factor of 40 per cent is fairly good, however, when the preponderance of connected lighting load is taken into consideration.

As stated above, load curves taken on a number of plants in the same line of manufacture or of a similar nature show the same tendency, as illustrated by the accompanying charts of textile loads—on khaki cloth, hosiery yarns, cord and twine. The load factors vary with the load operated after 6 p. m.

The refrigeration curve as shown here represents the

load on a plant refrigerating peaches and other perishables during the summer months. This load is very desirable, as it is practically steady all the year round, dropping off slightly in the winter months. Another type of industry with a high load factor is the ice-cream business. The load shows very little change during the winter months in this section, the demand for this delicacy remaining fairly steady.

The manufacture of farm implements may be considered seasonal business, and while the load does not drop off abruptly like other types, the curve follows

CHARACTERISTICS OF ONE PLANT OF EACH CLASS OF BUSINESS
(LOAD FACTOR CALCULATED ON BASIS OF THIRTY-MINUTE YEARLY DEMAND)

Class of Industry	No. of Customers	Maximum Demand, Kw.	Kw.-Hr. per Kw. of Maximum Demand	Load Factor, 8760 Hours, per Cent
Abattoir and packing houses	2	76	6100	69.5

the spring and fall demand for this class of goods. Although not illustrated in the chart shown herewith, the chair plant at times attains undesirable peaks of five to eight minutes' duration, which pulls the load factor down.

New York Lighting Companies Push Their Campaign

Bonds to Bind the Industry

Opportunity Presented by the Third Issue of Government War-Financing Obligations to Gather Together and Work Shoulder to Shoulder in Democracy's Cause—The Utilities' Chance to Aid

FOR the third time in a year the government is asking its people to lend their money to the cause of world freedom from the oppression of the Hun. To-day begins the national campaign for subscription to the third Liberty loan. At a higher rate than in the two previous issues—4½ per cent—the present loan is very attractive. It is so attractive that every home should have its bond.

To the electrical industry the third loan offers an especially attractive opportunity to help the government. The separate branches of the industry are talking more to-day of the necessity of working with the other branches—of strengthening the house from within, so to speak. The manufacturers, central stations, jobbers, dealers and contractors are beginning to look at one another now from a somewhat different angle and to recognize one another's strength in the industry's edifice.

One way to bring about better understanding is by gathering around a table for free exchange and interchange of thought and ideas. Another way is by working shoulder to shoulder to promote a cause that has no selfish attachments. Both of the ways are open in the Liberty bond campaign and naturally suggest themselves.

In each of the three weeks of the campaign there should be a meeting of the electrical men of the community for the purpose of seeing that every member of the industry subscribes for at least one fifty-dollar bond. For these meetings the local Liberty bond committee will gladly furnish speakers and literature and tell how to and how not to sell the bonds.

To do this a simple organization will suffice, but an organization of some kind will be necessary. It should be so worked out that there will be assurance that every electrical man will be called on by some one. Those who do not subscribe during the first call can be placed in a separate group to be called on during the third week by one person after another until the subscription is forthcoming.

It has been found during the two previous campaigns that efforts to secure subscriptions at meetings are futile. That the meetings are valuable is not denied, but their value lies in gaining the attention of those

attending and giving them something to think about when they get home.

The best way, as pointed out in previous issues of the ELECTRICAL WORLD, is by personal solicitation. Therefore to have the maximum of success every member of the electrical industry must be approached individually.

For this purpose it might be best to give to each member branch of the industry the task of securing the subscriptions of its members. Those not secured in the

first attempt can then be concentrated upon. The New York committee in this connection expects to secure maximum results from the contractors through the electrical inspectors. It is believed that a contractor will find it difficult to tell an inspector that he does not intend to subscribe.

One section of the electrical industry that has a greater opportunity to help the sale of bonds than any other is the electric light branch. Because of its contact with so many homes and business houses it has a chance to help the local committee. For the most part the campaign probably started at too late a date to allow of envelope stuffers with the bills for

March energy consumption. There is an opportunity, however, to send out Liberty loan literature with all bill receipts besides using the windows for display.

A large number of central stations in the two previous loans were of considerable assistance to the local committees. While a good many merely used the posters sent out by the publicity committee, there were a number of very original displays which attracted considerable attention.

One in particular, which drew mention by the local press and illustrates what can be done by lighting companies, was worked up by the Indiana Railways & Light Company. In this display a Liberty Bell about 2 ft. by 2 ft., made of heavy cardboard and painted in exact reproduction of the original, was made to ring by means of a cord running over large wooden pulleys painted to represent silver dollars, the device including a small pulley with a cord to which was suspended a "sack of money." The weight of this sack was necessary to cause the bell to return properly to the upright position when it had been tipped.

Central-Station January Operations

CENTRAL-STATION statistics for January give precise data on the effect of lightless nights and the Garfield order closing industries. Revenues of properties reporting to the ELECTRICAL WORLD show an increase of 9.4 per cent over January, 1917, and the output in kilowatt-hours gained 7.1 per cent.

These figures indicate that the Fuel Administration regulations, while undoubtedly curtailing both output and gross revenue, had no large effect upon these production totals. The question of the effect upon net revenue is one with which the compilation does not deal.

It is apparent that, as might have been expected, the normal gain in output was affected more heavily than the normal gain in gross revenue; that is to say, consumption by heavy power users was curtailed more than consumption by smaller consumers. Heavy power users evidently took more than their normal amount of energy on days when the regulations were not in effect; if their factories had not been thus stimulated, the decline in the rate of increase would have been still larger.

It is noteworthy that in spite of the influences operating to curtail production the necessity for central-station energy is so keen that increases are still maintained over the large gains of the last few years.

If the activity of some industries is arrested by changes due to the war, the demand upon other indus-

tries is increased by the national requirements. The net result, so far as central-station production is concerned, is that every kilowatt-hour which can be generated is needed.

Based on the statistics reported for 50 per cent of

STATION & OPERATING PRACTICE

A Department Devoted to Problems of Installation, Operation and Maintenance of Equipment for Economical Generation and Distribution of Electrical Energy

KEEPING BOILERS GOING IN SEVERE CONDITIONS

Inability to Get Repair Parts Owing to Congested Freight Conditions Leads to Adoption of Temporary Makeshifts That Prove Worth

During the cold weather of the winter months several of the power houses of the state institutions of the State of Illinois had to adopt makeshift repair methods to maintain steam heat in the radiators and electric service on the lines. Repair parts which were intended to keep the plants in operating condition were lost or delayed in transit. These plants were confronted with a problem similar to that of a public utility in that it was necessary to give continuous service, as the shutdown meant suffering and privation to the occupants of the institutions.

At one of these plants a 400-hp. water-tube boiler to which fuel was being fed by a chain-grate stoker went out of service owing to the gate of the stoker hopper becoming disabled. The gate tile had burned out, thereby permitting the gate to drop on to the chain grate and be carried over the fire, where it was completely destroyed. The emergency was met by constructing a new gate from material at hand, as follows: Some 12-in. by 24-in. (30-cm. by 60-cm.) tiles, used ordinarily for constructing the bridge wall, were drilled at one end to receive a U-bolt, the bolts being clamped over a piece of pipe so as to provide a continuous line of tile. The assembled tiles were then dropped into the gate guides and held in place by a strut fitted over the top of the coal hopper. The depth of the fire was regulated by placing shims under the pipe or removing them to raise or lower the improvised gate. This gate was used until the repair parts arrived.

Put Your Savings in the Trenches

PORTABLE SUBSTATION FOR SERVING EMERGENCY LOADS

Central Station in Northwest Stands Ready to Supply Electric Service to Industrial Plants When Isolated Plants Break Down

The Portland (Ore.) Railway, Light & Power Company has equipped a flat car with a converter, air-blast transformers and the necessary auxiliary equipment so that it can dispatch it to any industrial plant in its territory which has a railroad siding when a sudden demand for electric service is made. This portable substation is used to supply energy temporarily until permanent equipment can be installed. It has been found especially useful in serving factories when their isolated plants break down.

The equipment carried on this flat car includes a 400-kw. rotary converter, three 11,000/440-volt air-

blast transformers, a 28-in. (71.1-cm.) motor-driven blower and the necessary switching and measuring apparatus. The arrangement of this equipment on the flat car is shown in the accompanying illustration.

AIR-BLAST TRANSFORMERS AND ROTARY CONVERTER MOUNTED ON FLAT CAR

Over the equipment is built a wooden framework which can be covered with asbestos and tar paper to protect the apparatus from the weather. After the car is hauled to the place where it is to give service the weight is taken off the springs by jacking up the body, thus preventing excessive vibration during operation.

THREE-POINT MOUNTING OF FIELD RHEOSTATS

Ventilation Is Facilitated and Wiring Is Arranged So as Not to Interfere with Accessibility of Other Circuits

A convenient mounting employed in a New England generating plant for a five-section field rheostat is

VENTILATION FACILITATED BY THIS CONSTRUCTION

shown herewith. The resistors are in five parallel planes, with the central operating rod directly in line with the control handle on the switchboard panel in front. Each set of resistors is tied together by three

horizontal pipes bolted to strap-iron, the lower strap being fastened to a pedestal of wrought-iron pipe, the two upper ones being seated in a U-strap carried to a firm support on the switchboard panel. This construction affords excellent ventilation and enables the wiring to be carried behind the resistors and down past the buses and heavier cables at the rear of the board without any obstruction by small conductors of the aisle space between the board and the plant windows.

DRYING PIT DESIGNED FOR ELECTRICAL REPAIR SHOPS

Found to Be Especially Useful in Drying Apparatus Damaged by Floods—Details of Construction Given

A drying pit for electrical apparatus will be found useful in motor, transformer or other electrical repair shops, especially by central stations operating in districts susceptible to flood damage. The first cost of a drying pit with equipment is not excessive and will soon be saved if much repair work is under way. Drying apparatus in a heated container is cheaper than making a dry-out run on each appliance. Among the advantages of a drying pit is that it may be floored over and hence occupies no useful space. Furthermore, heavy machines may be lowered into a pit more easily than they can be placed in an oven.

CROSS-SECTION OF DRYING OUT PIT

PIT IN WHICH ELECTRICAL APPARATUS CAN BE DRIED OR BAKED AFTER BEING REPAIRED

A typical pit for a small shop may be constructed as shown in the accompanying drawing. Such a pit may be heated by any form of radiator. The pit referred to is equipped with a steam coil consisting of two complete turns of 1 1/4-in. (3.1-cm.) pipe placed at the bottom. To each side of the pit, 3 ft. (0.9 m.) below the floor level, is attached a 2-in. by 2-in. by 3/8-in. (5-cm. by 6-cm. by 0.95-cm.) angle, 9 ft. (2.7 m.) long. These support a movable gridiron 4 ft. (1.2 m.) long extending across the width of the opening. The gridiron forms a platform useful in supporting small motors, coils or other apparatus less than 3 ft. (0.9 m.) high, and serves the double purpose of increasing the storage space and holding the apparatus in the hottest part of the pit.

Ten feet (3 m.) above the pit and along its center line is a 10-in. (25.4-cm.) I-beam on which runs a trol-

ley and a 1-ton chain block, by means of which apparatus to be dried may be readily raised from a truck and lowered into any part of the pit. At one end of the pit a plug outlet is provided for lighting or testing purposes.

The pit is maintained at an average temperature of 85 deg. C. (185 deg. Fahr.). Small motors are ordinarily dried after rewinding for twenty-four hours, twelve before and twelve after dipping. Transformers are dried from twelve hours up, depending on the results of insulation tests.

COMBINATION LOAD BOX AND CALIBRATOR SAVES LABOR

Arranging Meter Tester's Apparatus in a Compact Single Unit Practically Doubles the Number of Tests One Man Can Make per Day

The best average record which meter testers of the Crawfordsville (Ind.) Electric Light & Power Company could make formerly, using the ordinary type of testing apparatus, was thirty-five single-phase meters

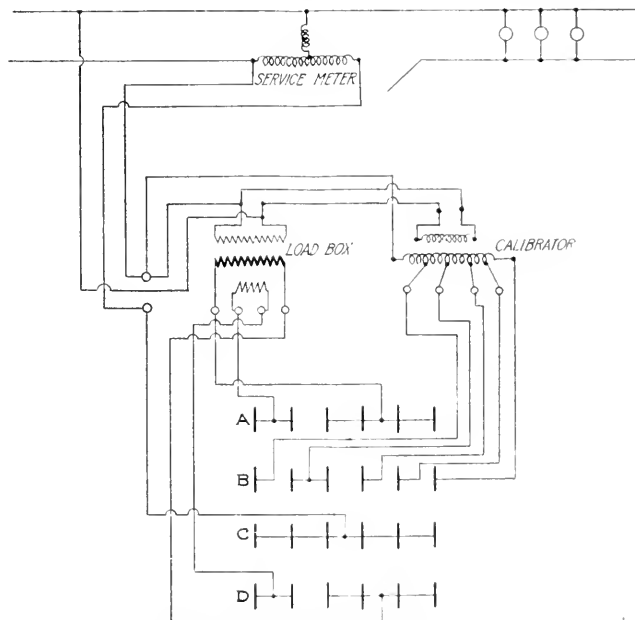

FIG. 1—WIRING DIAGRAM OF COMBINATION LOAD BOX AND CALIBRATOR

per day. After rearranging all of the apparatus into a single compact unit the meter tester was able to average sixty meters a day for a period of ten days. The single-unit set, which is shown herewith, included the load box and calibrator and all of the connections. F. H. Miller, manager of the Crawfordsville company, said that considerable time is saved by the use of this set because connections do not have to be changed frequently, only about one minute being required to prepare the outfit for testing.

Details concerning the construction of the set follow: The outfit complete weighs 30 lb. (13.6 kg.) and measures 15 in. (38.10 cm.) long by 7.5 in. (19.05 cm.) wide by 10.5 in. (26.67 cm.) high. It consists of a phantom-load box of the type made by the Eastern Specialty Company under the Herman & Mills patent, a Fort Wayne type M2 calibrator and the necessary con-

nections and switches. The load box has a range of 0.25 amp. to 50 amp. of non-inductive load. The calibrator has a range of 1 amp. to 100 amp. There is a 5-amp. light-load and a 5-amp. heavy-load adjustment.

To use the calibrator alone plug No. 1, shown in the lid of the outfit, is inserted to connect points *B* and *C* on the wiring diagram. To use the load box and the calibrator together plug No. 2 is inserted to connect

FIGS. 2 AND 3—SIDE AND TOP VIEWS OF COMBINED CALIBRATOR AND LOAD BOX

points *A* and *B* and *C* and *D*. The plugs are inserted through the holes marked 1 to 100, which correspond to the load desired. Spring switch clips are used for making contacts at the points *A*, *B*, *C* and *D*.

To conduct a test with this set, binding posts *A* are first connected with the service meter, a three-conductor cable composed of one potential wire and two current wires being used for all load conditions and tests. The potential connection is made at *P* and the calibrator control switch is connected at *S*. Iron connectors are used at *P* and *S*. By pushing the plug in the side of the pendent switch used with this outfit continuous operation is permitted. Pushing the end plug, which presses against a spring, causes the calibrator to assume the zero position.

Lend or Pay Higher Taxes, Which?

HOW TO REDUCE STRAINS ON PIN INSULATORS

Limiting Corner Angles for Pin Insulators and Other Requirements to Observe in Turning Transmission-Line Corners

Side strains on pin-type insulators and steel pins should be avoided when possible, but it is obvious that the various methods of turning corners without putting side strains on pins (such as the use of strain

FIG. 1—CONSTRUCTION WHICH INCREASES MID-SPAN CLEARANCE

insulators or other forms of dead-ends) cannot always be adopted owing to the expense of such special construction. With each type of line it is necessary to determine a limiting corner angle beyond which it may be considered unsafe to turn on pin-type insula-

tors. This angle will depend on the type of pin, the size of conductor and the length of adjacent span.

On 11-kv. suburban lines one company makes practice of turning corners on pins (double-armed) where the adjacent spans are no greater than 300 ft (91.4 m.), the wire not larger than No. 4 and the angle not more acute than 135 deg. Where the wire larger strain-insulator dead-ends are employed, and if the angle is sharper, either buck-arm construction or a vertical corner (with strain insulators attached directly to the pole) is installed. It has been found by experience that a side strain greater than that obtained with the angle specified will in time bend the steel pins. In turning corners of this type care should be taken to "split" the angle with the cross-arm; that is, angles *A* and *B* (Fig. 2) should be equal.

Pins having wide bases are to be preferred as they afford a greater bearing area on the cross-arm to resist bending. If that type of pin is used which has a malleable-iron top with a split thimble, it should always be set with the thimble slot parallel to the cross-arm. If set otherwise, the side strain will close the slot and the diameter across the threads will be reduced, causing the insulator to become loose.

FIGS. 2 AND 3—METHOD OF SPLITTING THE ANGLE AT THE CROSS-ARM; CROSSING OVER THE WIRE SAVES PINS

In approaching a corner of this type, where the three wires of a three-phase line are carried on a four-pin or six-pin arm, if normal position of the middle wire would carry it on the outside, it is sometimes advisable to cross over at the corner pole and take the inside position, as shown in Fig. 3. This not only reduces slightly the side strain on the pins holding the middle wire by increasing the angle, but tends to hold the arm more securely in position. When approaching a buck-arm corner under similar conditions the middle wire should be crossed over as shown. This procedure saves four pins and insulators (which would otherwise be necessary to carry the line around the outside of the pole) and is neater and safer.

Occasionally where one or more especially long spans are installed and it is undesirable to employ larger cross-arms to give greater clearances between conductors, staggering the middle wire will permit the same result, giving maximum clearance in the center of the span where it is most required. For instance, assuming the use of arms having the standard four-pin N. E. L. A. drilling, by this scheme the clearance between wires in the center of the span is increased from 14 1/2 in. (36.8 cm.) to 29 1/2 in.

OBJECTIONS TO INSISTING UPON CUSTOMERS' DEPOSITS

Discussion on Rule of Illinois Commission Covering
Methods of Handling Customers' Accounts
Shows Differences of Opinion

In a discussion of the tentative rule of the Public Utilities Commission of Illinois covering credit and customers' deposits, a few objections were voiced. It was noted that the rules were too definite in requiring that a company ask a deposit from every customer. There was considerable discussion also on the question of requiring customers' deposits at the end of twelve months. The discussion developed that there was practically no objection to following this policy with residential customers, but that there was an objection to it in connection with commercial customers. Certain classes of commercial customers are notoriously unstable, and while they may pay regularly for a considerable period of time they are entirely unscrupulous in the matter of paying final bills. In connection with establishing the amount of a deposit, the utilities contended that the deposit should amount to at least twice the amount of the estimated monthly bills, since collection methods employed usually permitted the customer to remain on the line for two months before being cut off.

PUBLIC UTILITIES' POINT OF VIEW

The Commonwealth Edison Company and the Public Service Company of Northern Illinois, presenting a brief on the rules, made the following comments on the rule for establishing credit:

The rule as drawn requires every new customer who does not own the premises in which the service is desired, or who owns real estate within the county, either to furnish a guaranty or who owns real estate within the county or to make a deposit. It gives the customer no other alternative, and gives no discretion in the utility, and actually operates to discriminate against the vast majority of customers whose credit is unquestioned and who are known to be well able to meet their bills promptly, irrespective of whether they own any real estate or not. In the first place, in a large city like Chicago, for instance, only a comparatively few people own any real estate, and in the second place, a great many people who are not owners of real estate are very well financially and have unquestioned credit with commercial houses, and a utility company in affording them the same means of establishing their credit that are adopted by other business concerns will, as experience has shown, take very little risk, and will in the long run give better satisfaction to its customers. It would be manifestly unfair and unnecessary, for instance, to ask a customer living in an expensive rented house or apartment, whose credit is unquestioned, to pay a deposit of \$5 in order to secure his monthly bills merely because he happens not to own any real estate and perhaps has not used the service of the company before. The fact that such a customer could easily afford to make the deposit is beside the issue. It is human nature to object at doing an unnecessary act and to regard any attempt to require the doing of such an act as an unjust intrusion upon one's rights. Long experience in dealing with hundreds of thousands of customers has clearly demonstrated

this to the credit departments of the Commonwealth Edison Company and the Public Service Company of Northern Illinois.

It is particularly necessary that a public utility company maintain good relations with its customers and with the public at large. Friction occurs often enough as things are, and utilities are already sufficiently subjected to the charge, unjust though it may be, of using arbitrary methods of dealing with their patrons. Any further cause of friction should be avoided if possible, and yet Rule 8 as drawn will operate to require the utilities of the State to put every new customer who does not own real estate, no matter how responsible he may be otherwise, to the inconvenience of furnishing a deposit or guaranty, as a condition to service, instead of taking such deposit or guaranty as at present only in the few exceptional instances where a customer's credit is shown to be poor or questionable. Rule 6, therefore, is not fair either to the public or to the utilities.

It is interesting to note, and directly bears out the foregoing criticism of Rule 8, that the Commonwealth Edison Company, after pursuing for years a policy of careful investigation of all new customers' credit, in 1917 required deposits from only 5 per cent of the customers connected to its mains during the year, the average amount of the deposit being \$9. This company has approximately 347,000 customers and now holds only about 17,000 deposits. The policy of the company in passing credits on applications for service in residences and flats has always been extremely liberal. It promptly turns on the light for any who send in written or telephone requests for service, the operator who turns on the light obtaining the signature to an application and this application being then passed through the credit department. If the customer has used the company's service before and has paid all his bills, he is not asked to make a deposit. If he gives satisfactory references or is employed in a permanent position paying only a moderate salary, his credit is passed without question. It is in general only those living in questionable places or women without any stated occupation or references who are required to pay a deposit. In the year 1917 131,718 applications for service in residences and flats passed through the company's credit department, and out of this number only 4047 deposits were required, or 3.25 per cent. In the case of applications for service in places of business it is the company's policy to require deposits in general only where the customer is just starting in business, or is unknown, or has no rating, or can give no references other than personal references. The location and character of the business govern the matter of deposits to a large extent. For instance, the experience of the company has demonstrated the advisability of requiring deposits from motion-picture theaters, saloons, restaurants, barber shops and other places of business subject to frequent change in ownership. In the year 1917 45,753 applications for service in business premises passed through the credit department of the company, and out of this number only 4541 deposits were required, or just about 10 per cent. The total number of deposits taken in the year 1917 from both residence and business customers was therefore 5.4 per cent of the total number of applications for service received in the year. On the other hand, the company's losses from unpaid accounts amounted in 1917 to only 0.36 of 1 per cent of the total amount billed during the year.

Cases were also cited before other commissions and courts to substantiate the fairness of the company's contentions in this matter.

POSTAL CARDS FOR BILLING

Oklahoma Properties Using Them Find Space Also for Advertising Purposes

In many ways government postal cards present a means of saving in billing. For one thing, the stock costs nothing. A number of central stations have come around to the use of postal cards for bills. The Oklahoma Gas & Electric Company at Kiefer and the Sapulpa (Okla.) Electric Company, under the management of H. M. Bylesby & Company, use similar cards,

GRANTING CREDIT UPON HOUSE-WIRING CONTRACTS

Method Employed by Middle Western Company in Cases Where Applicant Is Not the Full Owner of Property

In taking house-wiring contracts the credit standing of the customer should receive careful attention, for much of this business is done on other than a cash basis. The method used by one of the Middle Western companies in this connection is as follows:

On receipt of a house-wiring contract the name and location are entered in the receiving book, and a number is given as a means of identification. The location is then looked up through a firm employed for this purpose to see if the applicant's claim of ownership can be verified, the credit data are checked, and references are investigated as in commercial and residence contracts. If the investigation shows the applicant to be a good credit risk, holding title to the premises where the work is to be done, and the relation of the encumbrance to the valuation is not excessive, the contract is approved. If, however, the applicant is found to be buying the premises on contract of recent date and his equity therein is not sufficient to warrant the installation, the holder of title is urged to sign the contract jointly with the applicant. Should the records show the applicant to be buying the property on contract which has extended over a period of years and upon which a substantial sum has been paid, the owner of record is requested to sign a rider giving date of the contract of sale, the amount involved in the

contract, the amount the applicant has paid on same to date, and permission to the company to install the wiring, which permission carries the stipulation that all bills are to be paid by the applicant. Contract of this nature handled by this company average in price, including fixtures, from \$60 up, most of them being around \$200, but occasionally single contract amount to \$2,000 and more.

Help the Cause of Liberty

REDUCING THE EXPENSE OF HANDLING CUSTOM ACCOUNTS

Combination Gas and Electric Billing and Use of Billing Machines Effects Saving and Is More Satisfactory

The Central Illinois Light Company of Peoria, Ill. has worked out a system for handling customers' accounts that it believes is particularly adapted to fit its conditions. The system contains features, however, that seem also adaptable to the plans of other companies as measures of conservation. The features of the system lie in the combination gas and electric bill and in the machines for handling ledger work.

The company began using its present combination bill in January, 1917, although combination gas and electric billing went into effect in July, 1916. J. H. Thomas, chief clerk for the company, writing concerning this bill, said: "The advantages of the combined bill as I see them are, first, elimination of the sorting of meter-read slips and bills, thus allowing meter readers to give all their time to meter reading and bill distribution; second, ledger keepers are enabled to post credits, make delinquent notices and draw off balances in one-third less time than formerly; third, cashiers are able to handle customers faster, as it is no longer necessary for them to add the gas and electric amounts when the bill goes to the consumer with the net amounts extended. Also the cashiers require one-third less time in adding the coupons than formerly."

Mr. Thomas continued:

In January we replaced our long-hand billing with machine billing, and I consider this a real conservation measure, as our billing force was reduced to one-half of that formerly required. One operator and one stamping clerk now handle 29,000 meters per month. Part of our bills are extended by machine and part by rubber stamps. By test we have proved that extensions may be stamped twice as fast as they could be entered by machine. By analyzing our bills for several months we found that if we used 300 stamps we could stamp about 75 per cent of all extensions; hence our bill design is such that when the consumption in kilowatt-hours or in cubic feet is in excess of fifty (the limit with the stamps) the extension can be completed by machine. From our experience with machine billing we find that a saving of about 30 per cent has been effected in billing expense. The other advantages are a much neater bill and a reduction in the time required between reading and bill delivery.

Our bill is made out directly from the meter-read slip. We do not make a recapitulation sheet or use a carbon-copy ledger; therefore, of course, do not add meter readings, etc., it being the writer's opinion that this checking is a sort of "tail wagging the dog" proposition.

On Jan. 1, 1918, we also changed to machine-entered ledgers, and with these were further able to reduce our force. I am of the belief that this ledger installation is the first of its kind. We have used it but a short time, but a thorough preliminary test was given it. Actual working has maintained the results of the test. By its adoption we have been able to reduce ledger costs 30 per cent.

TECHNICAL THEORY & PRACTICE

Including a Digest of Important Articles Appearing in
the Scientific and Engineering Press
of the World

Generators, Motors and Transformers

White River Development in Northwest.—F. SCHMIDT.—Description of the hydraulic features of the White River development of the Puget Sound Traction, Light & Power Company, in which a 23,000-hp. water turbine is being installed. In order to prevent excessive variations in speed and voltage of the power system, it was necessary to use a very sensitive governor to control quickly the gates of the turbine. After a careful analysis of all precautionary methods employed was made it was decided to use (1) a surge reservoir, (2) pressure regulators, (3) air-cushion tanks. A combination of these three devices, together with an adequate fly-wheel effect in the revolving parts of the generators, made it possible to attain very satisfactory speed regulation. The article goes on to give details regarding different parts of the plant.—*Journal of Electricity*, Feb. 15, 1918.

Generation, Transmission and Distribution

Parallel Operation of Transformers.—F. KADE.—Transformers generally operate satisfactorily in parallel if their percentage ohmic and inductive drops are equal. In most cases it suffices if the short-circuit voltages are equal. There are, however, cases in which this condition is not sufficient; e.g., where two transformers are loaded differently, one each side of the circuit. Then the division of the loads between the two transformers varies with the relative magnitude of such loads. A number of such cases are described and the conclusion is reached that satisfactory parallel operation does not depend solely on the design of the transformers, but that the method of connecting them in circuit has an important effect.—*Science Abstracts*, Section B, Jan. 31, 1918 (abstracted from *Elektrotechnische Zeitschrift*, Oct. 11, 1917).

Electric Power Supply in England.—In this article the council of the Incorporated Municipal Electrical Association presents its views regarding the improvement of electric power supply in England. The statement reads, in part, as follows: "To insure that there shall be an adequate and economical supply of electric power it is necessary that the areas of supply should be selected according to the demand and facilities for obtaining suitable sites for generating stations. Generation should be on a large scale and extend over a considerable area, whereas distribution, which includes dealing with individual consumers, may conveniently be organized in smaller areas. The new areas of both generation and distribution should be continuous and will in many cases include within their limits places which at present are without supply. It is expressly emphasized that the best use possible should be made of existing systems of generation, transmission and distribution and also of the local knowledge obtained by the established undertakings. In many cases a joint board might be established for the generation of

all energy required in a large area and for the transmission of such energy by means of trunk mains, leaving the distribution to be effected locally. Some alternatives which have been adopted with excellent results in the supply of water and gas were suggested. Suitable provision should be made with regard to the rights and obligations of existing undertakings if the whole or any portion of an existing undertaking is transferred to a larger authority. The opinion was expressed that it would be a fatal mistake to put the supply of electricity entirely in the hands of public authorities. As regards having the control of the electricity supply vested in a central government authority, it was thought desirable that this authority should be strong on technical and inspectorial qualifications and should be responsible to Parliament.—*London Electrical Review*, Feb. 22, 1918.

Traction

Ventilated Motors During a Strenuous Winter.—R. E. HELLMUND.—The excessive troubles and breakdowns experienced during the past severe winter season with car equipments suggest the following questions with regard to the motors: (1) To what extent is the introduction of the ventilated type of railway motors responsible for breakdowns? (2) What can be done with regard to operation and maintenance to avoid a recurrence of the recent experiences in connection with the motors? (3) Is the ventilated motor a practical proposition and is it destined to survive? The following conclusions were the ones reached: That a certain amount of damage is done to the motor equipment owing to the dampness within the motor caused by snow and water conditions. The older so-called inclosed motors suffered more than the ventilated motors. Much of the snow causing the damage to the motor entered through the top commutator opening on account of missing or badly fitting commutator covers. Ventilated motors for a given continuous rating weigh less than non-ventilated motors and absorb less heat. Under ordinary operating conditions this is of little consequence, but under emergency conditions such as obtain while cars are bucking snowdrifts, pulling disabled cars home, etc., the ventilated motor, if worked to the limit of its continuous rating, is more liable to roast out than the old non-ventilated type. The extra weight of the latter and the larger mass can temporarily absorb, during heavy overloads of short duration, a certain amount of heat which tends to prevent overheating. A number of failures of ventilated motors have also occurred where the cars have been overmotored.—*Electric Railway Journal*, March 16, 1918.

Installations, Systems and Appliances

Standardization in South African Electric Supply Systems.—JOHN ROBERTS.—The author proceeds to consider the subject under the following heads: System—(1) Class of current, alternating or direct; (2) period—

city; (3) number of phases; (4) generating pressure; (5) transmission pressure; (6) supply pressure of distribution; (7) system of distribution network. Materials and Plant—(a) Sizes of bare and covered conductors for overhead work; (b) insulators; (c) system of cable laying for underground mains; (d) sizes of cables; (e) street lamp brackets; (f) meters; (g) plugs for heating appliances.—*London Electrician*, Feb. 8, 1918.

Improvement of Power Factor.—F. SCOUMANNE.—The first methods used in the improvement of power factor in large central stations applied only to the receiving apparatus; the idea of using the reactive current for this purpose by means of special appliances is a recent one. In the first part of an extended discussion of this subject the author, after a brief history of the problem and a statement of its present status, studies particularly the overexcited synchronous motor and the condenser equipped with a solid dielectric. He gives the complete theory of these two kinds of apparatus and compares their characteristics, coming to the conclusion that from almost every point of view the static condenser has considerable advantages over the synchronous condenser. The high price of the former and the lack of experience in its use are objections that time will overcome.—*Revue Générale de l'Electricité*, Feb. 9, 1918.

Electrophysics and Magnetism

Calculation of the Non-Sinusoidal Effective Emf. of an Alternator.—H. PÉCHEUX.—The calculation of the effective emf. of an industrial alternator in terms of the maximum emf. is laborious and necessitates calculating the coefficients of the Fourier series which represents the instantaneous emf. of the alternator. This article gives a method of attaining the desired result using only elementary mathematical processes.—*Revue Générale de l'Electricité*, Feb. 9, 1918.

Nature of the Ultimate Magnetic Particle.—ARTHUR H. COMPTON and OSWALD ROGNLEY.—In the opinion of the authors the ultimate magnetic particle is neither a group of atoms such as the chemical molecule nor the atom itself, which is the elementary magnet. "We must look rather to the atomic nucleus, as suggested by Merritt, or to the electron, as proposed by Parson, for the ultimate magnetic particle."—*Physical Review*, February, 1918.

Phenomenon of Voltage Surge in a Circuit Without Self-Inductance.—H. CHAUMAT.—In a note communicated to the Académie des Sciences the author described a phenomenon which at first sight appears paradoxical and which he thought had not previously been observed. The phenomenon consisted of a voltage surge in a direct-current circuit containing no self-inductance and including only condensers and resistors. It took place while the circuit was closed and all the connections remained unchanged. A mathematical demonstration of the phenomenon is given.—*Revue Générale de l'Electricité*, Feb. 9, 1918.

Units, Measurements and Instruments

Measurement of Small Inductances and Power Losses in Condensers.—ALBERT CAMPBELL.—The measurement of very small self-inductances in circuits having only two terminals is not difficult if the resistances are not high. One of the simplest ways of doing this is by

Heaviside's method, in which comparison is made with a known mutual inductance. It is easy to build a mutual inductometer of almost any desired lowness of range by stranding the windings of the coils. It is shown that the inductances of such resistances can be determined by the addition of the Kelvin double bridge to the Heaviside bridge. The author proceeds to describe the methods involved for the measurement, giving valuable data with mathematical calculations pertaining thereto.—*London Electrician*, Feb. 8, 1918.

Telegraphy, Telephony and Signals

Radio-Telephony.—ALFRED N. GOLDSMITH.—Thirteenth article of a series intended to direct university extension work. The author describes a system of radio-telephony control involving both an Alexanderson alternator for the direct generation of the radio-frequency energy and one or more pliotrons for the modulation and control thereof. Ferromagnetic control systems are also described.—*Wireless Age*, January, 1918.

Miscellaneous

Present Status of Insulator Depreciation.—C. E. OAKES.—Numerous experiments have proved that porcelain rapidly becomes an electrolyte with an increase in temperature. When it is also considered that porcelain which has absorbed more or less water is already an electrolyte, failures are to be expected. There are reasons for believing that a large percentage of the total failures are due to cracking of the porcelain in the insulators. The many factors which contribute to the mechanical stresses to which an insulator is subjected complicate the problem of ascribing causes to a given failure. Among the factors which cause undue stresses can be named: (1) Faulty design of the insulator, (2) use of materials having widely different temperature coefficients (that of porcelain is about one-half that of steel), (3) the stresses set up in the insulator due to the change in volume of cement under varying weather conditions, and (4) the gradual increase, with time, in volume of the cement. Investigations to determine the change of volume with temperature, variations, breaking strength of porcelain, etc., were outlined and useful information presented.—*Journal of Electricity*, Feb. 15, 1918.

Switchgear Standardization.—C. C. GARRARD.—In regard to knife switches, the author says that a standardization of the length of break, distance between the poles, sizes of terminals, current density and construction details is very necessary. When installing an oil switch on a large system the maximum power in kilovolt-amperes which it will have to rupture has to be considered. Large motors may be protected by a small choking coil. The time taken to blow a fuse depends upon the size and the degree of overload. The normal fusing current can best be ascertained by plotting a curve. For the construction of starters and regulators the copper-nickel alloys are suggested. Starters should be standardized as regards rating. Cellular compartments are especially favored by the writer for high-tension switching and busbar equipment. The horn gap in combination with lightning arresters should be standardized, as should choking coils. Of late, two methods for the protection of large systems have come to the front, namely, the static condenser system and the electrolytic.—*London Electrician*, Feb. 22 and March 1, 1918.

NEWS OF THE INDUSTRY

Chronicle of Important Events and General Activities in the Technical, Commercial and Manufacturing Fields

DAYLIGHT SAVING MAY

LEAD TO HIGHER RATES

President Edgar of Boston Edison Company Says
that Yearly Daylight Saving Would Influence
the Peak

President Charles L. Edgar of the Boston Edison company briefly commented upon the probable effect of daylight saving on the central-station industry at a hearing April 1 before the Massachusetts Gas and Electric Light Commission. The company's general rate schedule is under investigation.

Mr. Edgar said that if daylight saving were in effect all the year around it would have a decided influence upon the peak, and at the end of two or three years would not affect the central station unfavorably. The use would go down in the same proportion as the peak. "But if the peak is to remain the same by having the ordinary time in the winter the central station will lose in the seven months and not recoup any of the loss during the winter," said Mr. Edgar.

The speaker stated that the general theory is that with daylight saving the year around the peak would be reduced. This seems to be the effect in Detroit, which is the only place fairly comparable to Boston. England is so much farther north (London being in the latitude of Labrador and Boston of Italy) that British conditions furnish little assistance for comparisons with Boston data. English children have always gone to bed by daylight and have done so no more this year than before. Furthermore, England has lightless nights on account of air raids, and is "long" of coal whereas Massachusetts is "short" of coal.

Mr. Edgar said further, in part:

We have no idea what effect the daylight saving will have on us. All I can say is that, taking yesterday's output, there was a falling off of about 15 per cent. Of course, that was simply one day, and a Sunday, and we cannot yet tell what the result here is going to be. But if conditions here were similar to what they have been in England, we might have to raise prices 25 per cent and still lose money. When I say "we" I don't mean the Boston Edison company, but the industry as a whole. I cannot, however, conceive of conditions here being as bad as that, though there has already been an appalling falling off.

On the darkest winter nights we turn on our street lights at 4.40 o'clock. New York turns them on at 5.05 o'clock, because New York is further west. Both cities have the same general habit of storekeepers closing their stores at 5 o'clock. It has been very noticeable that our investment is tremendously higher than that of New York because of that fact. We have a peak in proportion to the business very much higher than they have. Now, that would be overcome if we had the daylight saving in winter, provided that people did not change their habits. There are people who will want to close their stores just about dark, regardless of whether it is 5 o'clock or 6 o'clock. Nobody knows what the psychological effect of that will be. That is not true in summer, because the darkness comes so late that it is after business hours, anyway; but if stores continue to close a few minutes after dark daylight saving will not be saving at all, it won't have any effect.

But, on the theory that stores close at 5 o'clock and that we won't turn on the street lights till 5.45, our peak, which would be ordinarily 95,000 kw., might not be over 85,000 kw. Therefore the industry, while bowing to the demand of the public for daylight saving, wishes that it might be done for the year, and there has been quite a tendency in Washington to make it for the year. But it hasn't been done yet. So, instead of having it a seven-month law, we would like to see it made a twelve-month law. But I have no idea what the effect is going to be, and I am free to say that I don't think anybody has any idea. It has never been tried in this latitude.

Detroit has tried it, and the situation there is rather curious. It is halfway between middle and central time. They have been half an hour out one way, and they will now be half an hour the other. Of course, that has a tremendous effect on them. And they have tried it a year. The effect in winter is even more pronounced. As a matter of fact, the Detroit curves show that their morning peak is greater than their evening peak, which is phenomenal. That has never happened in this country—has never happened anywhere.

As a matter of fact, one can read a newspaper in London at 10 o'clock at night anywhere, and where the necessity for lighting comes from 10 to 11 naturally there is not the same situation or the same effect as where it comes from 7 to 8. As far as Buffalo would be concerned, the situation would be much the same in some respects as in Detroit. Buffalo is on the ragged edge. It has been going according to Western time, and is now changed to Eastern time. It has been half an hour one way, and now will be half an hour the other way. But I don't think Buffalo has tried it.

We will not have any data on daylight saving until about May 20. It takes us two or three weeks to get our data for a month. It is not only a question of what the drop has been, but what the drop has been in any particular price. Unfortunately, the drop seems to be all coming on the 10-cent rate, because it is that kind of service that is affected by daylight and darkness. If the effect yesterday is any criterion, it would seem as though it was going to be equivalent to 2 or 3 cents on our retail price.

Liberty Bonds Are Safe and Sure

Working to Conserve Fuel in New York State

At a second conference of representatives of various state associations and light, power and heat companies of the State, held with the New York Public Service Commission, Second District, Albany, it was decided to co-operate with State Fuel Administrator Wiggins in the conservation of fuel in connection with the production of light, heat and power.

Those present were Chairman Hill, Public Service Commission; Gerritt Y. Lansing, Fuel Administrator, Albany; R. M. Cox, Middletown, representing the State Conference of Mayors; A. E. Cluett, Troy, representing New York State Manufacturers' Association; J. T. Hutchings, Rochester; Stuart Wilder, Mount Vernon, and H. W. Peck, Schenectady, representing power companies, and E. J. Cheney, engineer light, heat and power division of the Public Service Commission.

It was decided to begin a campaign to bring about conservation of fuel, and committees were appointed.

Fuel Administration for Water-Power Law

In Hearing Before Committee of Congress Charles E. Stuart, Technical Representative of Fuel Administration, Points to Necessity of Conservation in Fuel and Power

CHARLES E. STUART, technical representative of the United States Fuel Administration, made an extended argument in favor of the proposed House of Representatives' substitute for Senate bill 1419 during the recent hearings before the House joint power committee at Washington. These hearings have been reported in some detail in the *ELECTRICAL WORLD*. Mr. Stuart's argument dealt with the great importance of saving fuel and power and avoiding waste. It urges that there be a complete perspective of the entire power situation at some centralized point, as at Washington.

WATER POWER AND THE COAL PROBLEM

The coal problem, said Mr. Stuart, is one which calls for effective conservation measures to prevent a continued shortage of coal during the next twelve months. To avoid or alleviate this shortage, three alternatives are possible. These are, briefly, as follows:

(1) Direct curtailment of consumption of fuel; (2) increased efficiency in use of fuel, and (3) replacement of fuel power by other power.

Under the conditions existing during last January the first alternative was the only practical resort, Mr. Stuart continued. "Every effort is being made by the Fuel Administration, however," he said, "to avoid the necessity of similar recourse to this alternative in the future by securing increased efficiency in the use of fuel (and of power) and through the replacement of fuel by other power."

At the present time the efforts of the Fuel Administration along the lines of the first alternative are directed largely toward the curtailment of non-essentials, added Mr. Stuart. Its efforts toward securing increased efficiency in the use of fuel may be divided, first, into those for securing increased efficiency in combustion and in steam applications in heating and power plants of all kinds, and, second, into those for securing increased economy through greater centralization in the production of electric power.

"This latter method," Mr. Stuart said, "depends for its results upon the fact that the average small isolated plant will consume from 6 lb. to 10 lb. of coal per kilowatt-hour, whereas the consumption of the average central station will usually range from 2½ lb. to 5 lb. of coal per kilowatt-hour.

"The work of conserving fuel by the centralization of power is handicapped in some localities, such as Philadelphia and Pittsburgh, by the fact that the central power stations are already fully loaded and are thus not able to carry the increased load which would result from the addition of the loads now carried by isolated plants. In such cases there is sometimes an additional method of securing results by interconnecting power stations. Owing to the fact that the maximum loads on different stations usually occur at different hours, two plants, if interconnected, can usually supply a greater output than if operated separately.

"It may be stated in respect to these localities that

the question of conserving fuel is secondary to that of conserving loads of the vitally important war-material manufacturing plants. To do either in those sections which are short of power it will obviously be a case of enlarging the central stations, building isolated stations to handle individual loads or utilizing a third means, namely, the interconnection of power systems. The building of isolated stations should be absolutely discouraged, as a general rule, to which rule we consider there are important exceptions. The rule is based on the fact that the money spent in constructing an isolated station will usually develop a far greater generating capacity where used in the enlargement of an existing modern generating plant."

Mr. Stuart argued that the interconnection of power systems possesses far greater merit than does the enlargement of existing plants. Greater use is made of the equipment already installed, the cost of interconnecting for increased capacity should be less, and the class of material and of labor required to effect interconnection is less competitive with war-material requirements, both as regards the character of material used and as regards the labor requirements.

The average load factor, which in this case means the ratio of average load to maximum load of the plants of the United States, probably does not exceed 25 per cent, declared Mr. Stuart. This means that during certain hours of the day a large part of the capacity of the central stations of the country is not used. "It is our prime object to lay emphasis on this fact and on a means by which relief can be had expeditiously, and that is by interconnections of power systems," the Fuel Administration representative said. "Such interconnections through the diversity of load carried by different stations will render available considerable quantities of power and at a cost which would be negligible as compared with building new central-station plants or of increasing the capacity of those stations already built.

"At the same time, we do not want to underestimate either the cost or the difficulties incident to interconnections. There will usually be an amount of expenditure involved which, under the conditions resulting from our war finance requirements, would either represent a burden that the central stations cannot under present circumstances carry or else would necessitate government aid in such financing that would be impossible or would conflict with the efforts of the government."

INTERCONNECTIONS EAST AND WEST

Mr. Stuart remarked with respect to interconnections that the West has already gone a great deal further than the East, particularly in the case of California. The opportunity for interconnections in the East is equal to that which in the past has existed in the West, and the necessities of such interconnections to-day are far greater than those that existed in the West.

"There is the third alternative, which is the question of replacing fuel power by other power," said Mr. Stuart in resuming his argument. "In the case of hydroelectric development, such replacement would, of course, give a maximum saving of fuel, but only at a maximum expenditure of capital where it means the constructing of new works.

"It is questionable whether a great deal of saving as a result of the construction of new works will be possible while the war lasts; in fact, it is doubtful whether great outlays in such directions will be wise in view of the fact that such expenditure would conflict with other work of a more vital character to the conduct of the war.

"On the other hand, there exists an enormous field in the enlargement of plants now operating; for example, 750,000 barrels of fuel oil is being consumed by auxiliary steam plants serving the city of Los Angeles, Cal., and adjacent territory. The city of Los Angeles owns a hydroelectric system which furnishes the bulk of the power requirements, the deficiency being made up by the auxiliary steam plants. The hydroelectric development is capable of enlargement simply by the increase of additional generating machinery and transmission lines. Thus, at a relatively small cost, this fuel consumption could be saved, or, conversely, a considerable additional generating capacity would be developed. There are many examples throughout the country corresponding to the Los Angeles situation.

"Coming to the question of the aid which the government could most advantageously extend, we believe as follows:

"First—Assistance should be rendered the power systems wherever interconnections may be deemed practicable and advisable.

"Second—Financial aid should be rendered for the enlargement of central-station systems wherever such need is deemed essential in order to produce increased power, a radical fuel saving, or where there will be obviated what practically amounts to a duplication of investment, as in the case of the construction of isolated plants at this time.

"Third—There should be the necessary help to enable a complete systematization of the power situation of the entire country. Duplication of investment should be rendered impossible as a measure of conservation not only of capital but also of materials, labor and fuel.

"There should be at some centralized point, such as Washington, a complete perspective of the entire power situation which would prevent any of the now recognized errors or abuses such as exist in duplication of investment, fuel wastages, etc."

ADDITIONAL TESTIMONY ON THE BILL

C. F. Kelley, counsel for the Montana Power Company, said that the bill, while necessarily a compromise, was a subject for mutual congratulation and appeared to afford a workable measure upon which those who were desirous of developing this unused asset could meet the government.

Mr. Kelley agreed that unappropriated surplus accumulated from earnings in excess of a fair return on the investment should be deducted in computing the net investment, but suggested that such portion of such funds as had been reinvested in improvements and betterments should not be so excluded. He said that

inasmuch as the prospective applicant would be at a great deal of expense in making examinations and surveys, preparing maps, plans, specifications, estimates, etc., a preliminary permit should be exclusive to its holder.

A. P. Morrison of the Electro Metallurgical Company, Niagara Falls, spoke from the point of view of the user of power, to whom stability of service and of rates were of the first importance. No power can be developed on a franchise revokable at will, and a revokable contract is of no use to the user of power. He suggested an amendment to the bill to prevent existing projects coming in under the law having a chance to raise rates. Considerable capital has been driven to Canada and Norway on account of the more favorable conditions and greater assurance of more power there. Tariff considerations and the fact that the water powers of America are distant from the coast have a bearing upon the situation, also the fact that our streams are seasonal and intermittent.

What Does Liberty Ask?—Buy Bonds

DEFINITE AGREEMENT MADE ON WATER-POWER LEGISLATION

Special Joint Water-Power Committee of House of Representatives Will Incorporate in Shields Bill Features of Administration Bill

It is understood in Washington that the special joint water-power committee of the House of Representatives has agreed to incorporate in the Shields water-power bill passed by the Senate some time ago all the features of the so-called "administration" water-power bill agreed upon by the committee.

Senators are expressing satisfaction that a way has been found out of a legislative difficulty by the decision of the special committee of the House not to bring in the so-called "administration" bill as a separate measure. Some senators have entertained the idea that as the Senate has dealt with water-power matters recently and officially expressed itself in the Shields bill, there would be little opportunity for substituting the so-called "administration" bill from the House for the Shields bill in the Senate. The plan now is for the House to amend the Shields bill by incorporating the features of the so-called "administration" bill.

ELECTRICAL CONTRACT FOR NEW ARMY AND NAVY OFFICES

Work to Be Done by Lord Electric Company Under Sub-Contract—Largest Office Building in the World

A sub-contract for the electrical work on the proposed new office building in Washington for the War and Navy Departments has been let by the Turner Construction Company to the Lord Electric Company, New York. The building will be 1860 ft. in length and will have seventeen wings, with a depth of 560 ft. There will be 20,000,000 cu. ft. in the building and 10 miles of corridors. The structure will be the largest office building in the world.

It is better to loan your money than to lose it—as you are likely to do if the Germans win.

CALVERT TOWNLEY,

Assistant to the President Westinghouse Electric & Manufacturing Company.

NATIONAL PROGRAM FOR OUR LABOR AND CAPITAL

Comprehensive Plan Formed by the War Labor Conference Board—No Strikes or Lockouts
During the War

A comprehensive report and recommendations have been presented by the War Labor Conference Board, representing employers and employees, appointed in accordance with the suggestion of Secretary of Labor William B. Wilson to aid in the formation of a national labor program for the period of the war. In its letter the board says to Secretary Wilson, in part:

The commission presents, as a result of conferences, the following program:

That there be created for the period of the war a National War Labor Board of the same number and to be selected in the same manner and by the same agencies as the commission making this recommendation:

That the functions and powers of the national board shall be as follows:

1. To bring about a settlement by mediation and conciliation of every controversy arising between employers and workers in the field of production necessary for the effective conduct of the war.

2. To do the same thing in similar controversies in other fields of national activity delays and obstructions in which may, in the opinion of the national board, affect detrimentally such production.

3. To provide such machinery, by direct appointment or otherwise, for selection of committees or boards to sit in various parts of the country where controversies arise, to secure settlement by local mediation and conciliation.

4. To summon the parties to the controversy for hearing and action by the national board in case of failure to secure settlement by local mediation and conciliation.

If the sincere and determined effort of the National Board shall fail to bring about a voluntary settlement, and the members of the board shall be unable unanimously to agree upon a decision, then and in that case and only as a last resort an umpire appointed in the manner provided in the next paragraph shall hear and finally decide the controversy under simple rules of procedure prescribed by the national board.

The members of the national board shall choose the umpire by unanimous vote. Failing such choice, the name of the umpire shall be drawn by lot from a list of ten suitable and disinterested persons to be nominated for the purpose by the President of the United States.

The national board shall refuse to take cognizance of a controversy between employer and workers in any field of industrial or other activity where there is by agreement or federal law a means of settlement which has not been invoked.

In the appointment of committees of its own members to act for the board in general or local matters, and in the creation of local committees, the employers and the workers shall be equally represented.

The representatives of the public in the board shall preside alternately at successive sessions of the board or as agreed upon.

The board in its mediating and conciliatory action and the umpire in his consideration of a controversy shall be governed by the following principles:

THERE SHOULD BE NO STRIKES OR LOCKOUTS DURING THE WAR.

Right to Organize.—The right of workers to organize in trade unions and to bargain collectively, through chosen representatives, is recognized and affirmed. This right shall

not be denied, abridged or interfered with by the employers in any manner whatever. The right of employers to organize in associations of groups and to bargain collectively, through chosen representatives, is recognized and affirmed. This right shall not be denied, abridged or interfered with by the workers in any manner whatsoever. Employers should not discharge workers for membership in trade unions nor for legitimate trade union activities. The workers, in the exercise of their right to organize, shall not use coercive measures of any kind to induce persons to join their organization nor to induce employers to bargain or deal therewith.

Existing Conditions.—In establishments where the union shop exists the same shall continue and the union standards as to wages, hours of labor and other conditions of employment shall be maintained. In establishments where union and non-union men and women now work together and the employer meets only with employees or representatives engaged in said establishments the continuance of such condition shall not be deemed a grievance. This declaration, however, is not intended in any manner to deny the right or discourage the practice of the formation of labor unions, or the joining of the same by the workers in said establishments, as guaranteed in the last paragraph, nor to prevent the War Labor Board from urging, or any umpire from granting, under the machinery herein provided, improvement of their situation in the matter of wages, hours of labor or other conditions, as shall be found desirable from time to time. Established safeguards and regulations for the protection of the health and safety of workers shall not be relaxed.

Women in Industry.—If it shall become necessary to employ women on work ordinarily performed by men, they must be allowed equal pay for equal work and must not be allotted tasks disproportionate to their strength.

Hours of Labor.—The basic eight-hour day is recognized as applying to all cases in which existing law requires it. In all other cases the question of hours of labor shall be settled with due regard to governmental necessities and the welfare, health and proper comfort of the workers.

Maximum Production.—The maximum production of all war industries should be maintained and methods of work and operation on the part of employers or workers which operate to delay or limit production, or which have a tendency artificially to increase the cost thereof, should be discouraged.

Mobilization of Labor.—For the purpose of mobilizing the labor supply with a view to its rapid and effective distribution, a permanent list of the number of skilled and other workers available in different parts of the nation shall be kept on file by the Department of Labor, the information to be constantly furnished by the trade unions, by state employment bureaus and federal agencies of like character, by the managers and operators of industrial establishments throughout the country. These agencies should be given opportunity to aid in the distribution of labor, as necessity demands.

Custom of Localities.—In fixing wages, hours and conditions of labor regard should always be had to the labor standards, wage scales and other conditions prevailing in the localities affected.

The Living Wage.—The right of all workers, including common laborers, to a living wage is hereby declared. In fixing wages minimum rates of pay shall be established which will insure the subsistence of the worker and his family in health and reasonable comfort.

The report is signed by the following: Loyall A. Osborne, L. F. Loree, W. H. VanDervoort, C. E. Michael, B. L. Worden, William H. Taft, Frank J. Hayes, William L. Hutcheson, Thomas J. Savage, Victor A. Olander, T. A. Rickert and Frank P. Walsh.

An invincible morale in our fellow countrymen is of the highest importance in winning the war. One of the surest ways to develop and maintain morale is to furnish unstintingly the sinews of war. Buy Liberty bonds and be an upstanding citizen.

of L. K. Comstock & Company, New York.

BOSTON ELECTRICAL MEN IN LIBERTY LOAN PARADE

Edison Electric Illuminating Company Employees,
to Total of 1000, Expected to Take Part in
Starting the Campaign

To signalize the start of the third Liberty loan campaign at Boston on April 6 a great parade was planned in which it was expected that the electrical industry would be largely represented. President Charles L. Edgar of the Edison Electric Illuminating Company of Boston announced his intention to march, and it was expected that at least 1000 Edison employees would take part, with the company band of forty pieces leading the contingent and the company service flag with 300 stars flying as the contingent marched through the streets. Charles H. Parker, superintendent of the generating department, was appointed marshal of the company forces.

J. W. Cowles, superintendent of installations, has been made chairman of the company's Liberty loan committee. On the first and second loans the 2000 employees of the company subscribed to \$158,000 bonds, and the company in its own name for \$530,000. T. K. Cummins, treasurer, addressed groups of employees in the earlier campaigning, and in the main the loans were placed through the Wildey Savings Bank, Boston.

The general plan was for one representative from each department to collect the subscriptions and make the deposits. The Boston company did not purchase bonds on behalf of employees, but co-operated fully with all local banking agencies in regard to the loan and devoted considerable editorial and reading space in the company publication, *Edison Life*, to the cause. This paper emphasized the desirability of the slogan "Invest in a bond," in preference to the popular "Buy a bond" war-cry.

Prior to the second Liberty loan the company paper said editorially under "Automatic Saving": "It is not the rich man who will help the most by investing, for the rich always save, and, furthermore, the money he has is of more importance in helping to keep alive the industries, such as farming, railroads and factories, for they are as vital to the war as the men who fight. The man who spends his salary on himself is the kind that must change his ways. He must ask for less personal service, for service is labor, and labor counts now. The saving that is necessary is the new saving, not turning the old saving into new channels."

Electrical men should be the most progressive people in the country, and, as the paramount war problem is to supply the government with all the funds needed, every electrical man should show the progressiveness and the effectiveness of the fraternity as a whole by the quantity and quality of the work he does to make the third Liberty loan a pronounced success.

HENRY L. DOHERTY,
President Cities Service Company.

War Training Course

A war training course for electricians and telephone men needed for the United States Army has just been published by the federal Board for Vocational Education. It consists of thirty-six lectures and four classroom, field and shop units on electric wiring, testing, motors and generators, and telephone work. The instruction book is known as Bulletin No. 9 and may be had free on application to the federal Board for Vocational Education, Ouray Building, Washington, D. C.

Some Offer Lives—Lend Your Money

MIDDLE WEST INTERESTED IN FINANCE CORPORATION BILL

Going Rates for Money the Principal Point of Concern with Executives—Typical Loan Costs About 10 per Cent

Middle Western central-station executives are watching with considerable interest the steps in the passage of the finance corporation bill.

The prices which are being paid for money are shown in the typical case of the Louisville Gas & Electric Company. Bankers are now selling the notes of this company on an 8 per cent basis and the money costs the company close to 10 per cent. Notes now being sold will care for another note-issue maturity and add about \$900,000 cash to the treasury. The company has \$10,000,000 of bonds falling due July 1. The banking syndicate which is selling the notes has offered to finance either bond or note issue for refunding, but the cost of new money would be so great that the officials believe the federal government will assist as soon as the finance corporation act is passed. The company must either pay at least 10 per cent for short-term money or contract to pay 6½ per cent, perhaps more, over a long term of years.

Another and interesting sidelight on public utility financing recently came out in Indiana when fire destroyed the municipal light and water works at Attica. The loss was only about \$40,000, but the city was already bonded so nearly to its lawful limit that funds could not be provided to rebuild the plant. To get out of the difficulty private capital was added to what capital the city could raise so that the station is now being replaced. On the other hand Tacoma, Wash., is getting ready to vote on a five-million-dollar bond issue for public utility extensions which include in their scope even the purchase of the street railway property.

The conference agreement on the war finance corporation bill has been presented to Congress. Several important changes have been made in the measure and they represent a compromise between the Senate and House views.

Never Too Old to Buy Bonds

COLONEL P. JUNKERSFELD RESIGNS FROM ASSOCIATION

Executive Committee of Association of Edison Illuminating Companies Accepts Resignation of President with Regret

The executive committee of the Association of Edison Illuminating Companies held a brief meeting at association headquarters, New York, on March 21.

A communication from President Peter Junkersfeld, under date of Feb. 14, 1918, was read, in which he tendered his resignation as president of the association, the reason given being that his increasing military duties prevented him from giving his proper attention to the affairs of the association. Mr. Junkersfeld has been serving at Washington as major in the Quarter-

master's Corps of the National Army for over a year, and was promoted recently to the rank of lieutenant-colonel. The committee was very loath to lose his leadership, but realized that no other course was open but to accept his resignation with great regret.

As the general business conditions which made it desirable to dispense with the customary convention last year have not materially changed in the interim, it was decided by the committee that the association would hold a business meeting only this year. This will be held in New York on Sept. 10, and will be similar to the brief meeting held in September of last year, unless the plan now contemplated is changed at a later date.

Win the War—Lend for Liberty

WESTERN RED CEDAR MEN MEET IN SPOKANE

Demand in 1917 About Normal, but Production Below Normal, Owing Largely to Labor Trouble
—O. S. Hanson Elected President

The thirteenth annual meeting of the Western Red Cedar Association was held in the Davenport Hotel, Spokane, Wash., on March 21. The meeting was called to order by O. S. Hanson, vice-president, in the absence of F. C. Culver, president.

A general discussion took place relative to market conditions prevailing during the last year. It was the consensus of opinion that the demand for Western red cedar poles during 1917 was about normal, but that production was considerably below normal owing largely to shortage of labor and trouble experienced in connection with the I. W. W. agitation. It was generally agreed that the actual cost of production has increased at least 50 per cent during the last year.

W. M. Leavitt, as chairman of a special committee in charge of the matter of arranging and conducting a series of comparative strength tests of the various kinds of poles, reported that nothing had been done in the way of actually carrying on the experimental tests contemplated. The committee gave the matter careful consideration and was unanimous in the opinion that it was not a good time to conduct the proposed tests, making this recommendation to the association. The matter will be taken up for consideration at a more opportune time.

A motion was made and unanimously carried that the new president send a telegram to Glenn A. Clark, formerly secretary-treasurer of the association, now serving in the Quartermaster's Corps at Camp Joseph E. Johnston, Jacksonville, Fla., regretting the fact that it was necessary to accept his resignation and sending from the entire membership best wishes for his success and early return.

Officers were elected as follows: President, O. S. Hanson, Spokane, Wash.; vice-president, R. G. Jones, Ione, Wash.; directors, E. T. Chapin, Spokane; L. A. Page, Jr., Minneapolis; J. M. Montgomery, J. E. Seaman, Spokane, was appointed secretary and treasurer.

Back Up the Bullets—Money Talks

ACTIVITIES OF THE NATIONAL COMMITTEE

Report of Work of the National Committee on Gas and Electric Service in War-Time Conditions

In last week's issue of the *ELECTRICAL WORLD*, page 688, a partial report of the National Committee on Gas and Electric Service, of which J. W. Lieb is chairman, was published. Other matters were discussed in the report as follows:

The committee has received a communication from the War Industries Board in reference to a possible demand for various government plants, to the effect that the public utilities may feel assured they will be given a full hearing on the subject before any of their machines are requisitioned. The committee is consulted by the various branches of the War Department when it is necessary to requisition machinery that may be under order for the electric light and power companies. In this way if machines must be taken they will be taken where their withdrawal will cause the least disturbance to operating conditions. In several cases where the War Department had planned to take machinery for the purpose of installing its own plants, the committee has been able to show where there was already available power, thus making it unnecessary to construct any new individual plants.

A recent situation arose which was called to the attention of the committee concerning a supply of electrical energy for a large munition manufacturer in Alliance, Ohio. It was represented that the power was not available in Alliance and negotiations had been entered into for the building of a transmission line from a neighboring city, approximately 14 miles distant, to serve this manufacturer. This action was strongly protested against by the Alliance Gas & Power Company, and while the committee could not take any position as favoring one or the other utility, it brought the representatives of the two utilities together, with the result that arrangements were satisfactorily perfected for abandoning the proposed expensive transmission line and securing the available service in Alliance.

The Fuel Administration is about ready to issue its plan for the zoning of coal, that is, assigning certain zones of production to certain zones of consumption. In this way a great deal of cross-hauling will be avoided. It has been found, however, that it would be almost impossible to zone the gas coal output, and it is proposed to issue special permits or licenses for this class of fuel. It is very doubtful if the situation as at present existing will be greatly disturbed, especially in the eastern part of the United States, and it is proposed to furnish New England with approximately two-thirds of her coal supply by water.

As a very large percentage of coal contracts expire about April 1, there is some confusion or doubt as to their renewals, and some of the public utilities are experiencing difficulty in arranging for their coal for the current year. After the zone system has been established by the Fuel Administration, this matter will no doubt clear itself up.

At the request of Dr. Garfield, the committee is endeavoring to secure from the central stations the location and names of isolated plants in their communities. This information is sought by the conservation department of the Fuel Administration, which is making a careful analysis of the fuel condition throughout the United States with a view to preventing a repetition of the dangerous condition in which the country was placed during the last memorable year and winter, due to the shortage of coal. It is extremely important that the electric light and power companies send in these lists as early as possible.

The committee is working in close co-operation with the Fuel Administration and information is being procured from the public utilities as to their requirements for the coming year. It is the intention to take care of the full requirements of the public utilities at as early a date as possible.

The committee is receiving from the public utilities applications for help in obtaining relief from embargoes and assistance in procuring express deliveries of electrical material.

The Quartermaster's Department and the aviation division of the Signal Corps have sought the assistance of the committee in obtaining information from public utilities in communities where they are about to establish large warehousing and other projects as to amount of power available for their purposes. In all the communities thus far considered there is a sufficient supply of energy, thus making unnecessary the installation of any governmental isolated plants.

Lend Freely for Liberty's Sake

OPERATING PROBLEMS AT WISCONSIN CONVENTION

Increasing Hydroelectric Plant Efficiency, Better Distribution Systems, Co-operating with Contractors and Solution of War Problems Are Topics

The program of the first day's session at the convention of the Wisconsin Electrical Association at Milwaukee March 27 and 28 included papers mainly on rates and rate increases. On the second day all papers except that of M. C. Ewing of Wausau dealt with operating problems.

Daniel W. Mead, consulting engineer, of Madison, speaking on "Increasing the Output of Hydroelectric Plants," divided his topic into subjects, "Saving Head" and "Saving Water." Under the former he discussed losses that occur in the headrace due to velocities above 3 ft. (0.9 m.) per second in low-head plants, to racks without specially designed bars, to improperly designed tailraces and to leakages through dams. From the latter cause enough water has been known to escape to cause a loss of \$75,000 a year. He criticised severely the policy of many waterwheel manufacturers who have been in the habit of selling wheels which are considerably underrated.

L. M. Burch, president of the Electrical Supply Company, Madison, presented an able explanation of the aims and purposes of the new association of Wisconsin electrical contractors and dealers, and solicited the co-operation of central-station executives in carrying out the plan for better merchandising.

George E. Wagner, superintendent of plant for the Madison Gas & Electric Company of Madison, Wis., pointed out the advantages of three-phase, four-wire distribution as compared with the ordinary 2300-volt delta-connected system. In the discussion of this paper A. J. Geodjen pointed out that an opportune time to investigate the advisability of changing from delta to star connection is when additional feeder capacity is needed.

M. C. Ewing, secretary-treasurer of the Wisconsin Valley Electric Company, Wausau, Wis., in a paper entitled the "Utilities and the War," discussed the urgent need for rate increases and closer study of labor.

The paper on "Metal Electrode Welding," by Dean Treat, manager of the Wisconsin Railway, Light & Power Company, La Crosse, Wis., pointed out the savings which can be made by using electric welders in laying street railway track and in repairing machinery and apparatus in the company's shops.

Officers elected for the ensuing year were: President, John St. John, Madison; first vice-president, Raymond Smith, Oshkosh; second vice-president, W. C. Lounsberry, Superior; third vice-president, A. G. Babson, Watertown; secretary, J. P. Pulliam, Green Bay.

THE ILLINOIS COMMISSION SUSPENDS FREE EXTENSIONS

Customers of Chicago Companies Must Pay for Lines During Period of the War—Companies Com-mended for Patriotic Stand

On Nov. 24, 1917, the Commonwealth Edison Com-pany and the Public Service Company of Northern Illinois filed with the Public Utilities Commission of Illinois a petition for the suspension during the period of the war of Rule 31 of the rules establishing stand-ards of service for gas and electric utilities. Rule 31 provides for free extension to prospective customers, provided that the line extension does not require more than twice as many poles at standard spacing as there are individual applicants. It also provides for charging for extensions above the free limits. The petition was contested by attorneys for several real estate boards in the territories of the petitioning utilities.

In its order on this case issued March 19 the commis-sion found:

That present conditions warrant a modification of the rules of the commission governing the making of exten-sions for serving new business, and that by the modified rules the petitioners may require a deposit from custom-ers who desire an extension of the petitioner's circuits in the amount of the cost of such construction, but that such a cost used as the basis for deposit would not include any amount for distribution transformers, for service connec-tions of ordinary lengths extending from the pole lines or underground conduits to consumers' premises, or for con-sumers' meters, and that service should be rendered to any consumer complying with these deposit conditions unless an individual case is of such character that it appears that the revenue anticipated from the extension will not pro-vide at the expiration of five years an adequate return upon its cost.

The commission further finds that in the case of exten-sions made for power service repayment of the deposits collected should be instituted immediately upon the cessa-tion of the war, and that the amount of such monthly re-payments should not be less than 25 per cent of the net bill for service, and that in the case of extensions made for lighting service repayment of the deposits collected should be made monthly at a rate of 25 per cent of the monthly bills, and that such repayment should be instituted with the first bills for service rendered.

The commission further finds that interest should be paid at the rate of 5 per cent per annum upon that portion of the deposit held by the petitioners which exceeds the cost of a free extension as defined by the original Rule 31 until such a time as the repayment shall have amounted to the cost of such free extension, and that interest at the rate of 5 per cent per annum should be paid upon the entire deposit until such time as repayments are instituted in accordance with the conditions herein set forth. In securing interest due in order to avoid the complication of interest computa-tions on various amounts, such interest after repayments have been started may be computed over the entire period for which it is to be paid upon one-half of the gross amount of the excess deposit.

It should be noted in connection with this decision that the requiring of the utilities to refund the amount of the line extensions to the customers is in line with what have been the policies of both the Commonwealth Edison Company and the Public Service Company of Northern Illinois in the past.

It is of further interest to note that the commission in its comments upon the case said:

In their petition the applicants appear to be governed by patriotic motives to an extent fully as great as by any pecuniary advantage which might result from deferring ex-tension until a more advantageous time. From the stand-

point of personal interest, the extension of utility service involves the payment of larger sums of money for lines and station capacity and other necessary improvements than would be necessary for the development of the systems under normal conditions. From a patriotic standpoint it involves the employment of material and labor of which the country faces a scarcity, and the utilization of capital which may be necessary for governmental needs in the prosecution of the war.

Buy Bonds, Still More Bonds

COMMITTEE'S TRIBUTE

TO JOHN P. SPARROW

Prime Movers Committee of the National Electric Light Association Pays Respect to Memory of Old Associate

In the issues of March 23 and 30, 1918, the ELEC-TRICAL WORLD referred to the death of John P. Spar-row, chief engineer of the New York Edison Company. The members of the prime movers committee of the Na-tional Electric Light Association have passed resolu-tions on their old associate, a copy of which has been received from J. M. Graves, the chairman, as follows:

John Porterfield Sparrow, for many years chief engineer of the New York Edison Company, in charge of construc-tion and operation, a member of the prime movers com-mittee of the National Electric Light Association in 1911, 1916, 1917 and 1918, died March 18, 1918. Mr. Sparrow was one of the most eminent designing and oper-ating engineers in the world, having been the son of a distinguished engineer, through whose efforts he received a thorough theoretical and practical training in his pro-fession both in the United States and Europe. He had been identified about thirty years with the electrical indus-try, in which he had become an influential figure.

As a member of the prime movers committee Mr. Spar-row was an enthusiastic and untiring worker, revealing wonderful foresight in anticipating operating and construc-tion problems and indicating rare ingenuity in devising methods for obtaining efficiency in power-generating sta-tions. His intimate scientific knowledge and his long prac-tical experience ripened his judgment and gave his opinions judicial weight. His was a delightful personality, lovable, courteous, patient, admired and respected. His death has been a severe personal loss to the members of the com-mittee and it will leave a vacancy which time alone may fill.

COMBINATION EXPORT TRADE

BILL IS UP TO CONGRESS

Conference Report on Webb Measure Presented to Both Houses and Quick Action Is Now Expected

The conference report on House bill No. 2316, known as the Webb bill, for the promotion of export trade, has been presented to both houses of Congress. Only minor changes are made in the bill by the conference report, and it will be adopted and signed by the President soon.

Some of the minor amendments to the bill pre-sented in the conference report have the effect of ex-cluding from the comprehensive definition given in the section of "export trade" the selling of goods, wares and merchandise for resale as well as for consumption within the United States or any territory thereof.

Current News and Notes

Timely items on electrical happenings throughout the world, together with brief notes of general interest.

Report on Taunton Plant.—William Plattner has completed an extensive report on the operations of the Taunton (Mass.) municipal lighting plant.

Rate Increase in Oklahoma.—The Oklahoma Gas & Electric Company has been granted authority by the State Corporation Commission to increase electric rates approximately 10 per cent.

John Fritz Medal.—J. Waldo Smith will be awarded the John Fritz medal on April 17 at the Engineering Societies Building, New York, for his achievement as an engineer in construction of the Catskill aqueduct for New York City.

Dayton Company Earnings.—The annual report of the Dayton (Ohio) Power & Light Company shows gross earnings in excess of \$1,880,000, an increase of 16 per cent over the previous year, and operating expenses of more than \$1,266,000, an increase of 26 per cent. Net earnings were \$624,407.

Special Electrical War Courses.—Special electrical war courses for enlisted men are being given at the Carnegie Institute of Technology, Pittsburgh. Instructors are wanted to teach in the necessary subjects. The Carnegie Institute especially desires to hear from a few who could come for periods of two to six months.

Workman's Compensation.—The *Workman's Compensation Law Journal* is now issued monthly by the C. C. Mine's Sons Company, New York. It contains all current decisions of all courts relating to workmen's compensation, the federal cases appearing first and the state court cases following. There are now thirty-seven states and three territories in which workmen's compensation statutes are in force, and the number of awards and rulings by the various state boards and commissions which are being passed upon by the appellate courts is constantly increasing.

Milwaukee May Defer Public Improvements.—Oliver C. Fuller of the Wisconsin Trust Company, Milwaukee, who is also the Milwaukee member of the auxiliary committee of the capital issues committee of Washington, D. C., recently addressed the members of the Public Debt Commission, the city officials and the members of the finance committee of the city council on the inadvisability of floating bonds for public work and improvements that are not absolutely necessary. The aim of the government, according to Mr. Fuller, is to eliminate such work and to create a condition whereby all men in all lines of work can apply their ef-

forts to government activities and to the war industry. Milwaukee has about \$6,000,000 in bond issues to be voted on this spring, and it is said to be the opinion of some of the city officials that not all of the work to be carried on from the proceeds of the sale of these bonds is imperative. One item in the proposed bond issue is \$500,000 for electric street lighting. The other items are sewers, schools, bridges, grade crossings, park improvements and city building.

Tokio Plans Electric Exposition.—The first electric exposition in Japan will be held in Ueno Park, Tokio, this spring, as part of the commemoration of the quarter-century anniversary of the Japanese Electrical Industrial Association. Ueno Park is one of the greatest attractions of Tokio to visitors in cherry-blossom time, and the date has been selected so as to give to several million Japanese a practical education in electricity and its many varied applications. Among the special displays to be shown is a large-sized working model of a modern hydro-electric plant, with glass-covered Pelton wheel to show the interior working; electromagnetic demonstrations in loading heavy materials and in resisting a tug-of-war by a crowd of athletes; electric blooming and withering of flowers, and floating bodies by electric induction. Actual demonstrations of lightning, its effects and prevention, of welding of metals and separation of ores will be given. Besides these, special "electric days" will be set aside by the city authorities, during which all the electric lights in the city will be kept burning late into the night.

Value of Columbus Electrical Property.—The value of the property used by the Columbus Railway, Power & Light Company in electrical operation, except for street railway and district heating, is \$7,105,808, according to an appraisal filed by the company with the Ohio Public Utilities Commission. The appraisal was ordered by the commission in June, 1915, after the company had appealed a rate ordinance. Engineers representing the commission have their appraisal almost completed, and when they are ready hearings will be begun. Company figures follow: Land, \$219,014; building and structures, \$373,033; power station equipment and coal, \$1,437,030; distributing system, \$1,896,802; miscellaneous, \$168,034; total physical property, \$4,067,237; property not used in electrical operation, \$11,429; total physical property used in electrical operations, \$4,055,808; collateral: preliminary expense and cost of financing, \$400,000; administration and general, \$1,000,000; cost of attaching business, \$400,000; working capital, \$250,000; miscellaneous, \$1,000,000; total collateral, \$3,050,000; total property used in electrical operations, \$7,105,808. The rate fixed by ordinance for a five-year period, beginning on Dec. 27, 1915, was 5 cents net or 6 cents per kilowatt-hour, with 16 2/3 per cent discount if paid before the tenth of the month. The old rates are 8 cents gross and 7 cents net.

Recent Court Decisions

Findings of higher courts in legal cases involving electric light, power and other public utility companies.

Low-Hanging Wires.—Negligence in the maintenance of a telephone wire across a public highway is sufficiently established when it is shown that the wire hung so low as to interfere with a customary use of the highway, the Supreme Court of Kansas held (169 P. 197). When a plaintiff has proved that he sustained injuries through the dangerous situation of a telephone wire hanging across a public highway the burden passes to the defendant to show that the dangerous situation of the wire was not due to the act of the defendant and had not existed for such length of time as to charge the defendant telephone company with notice of its defective condition.

Damages Resulting from Failure to Furnish Service.—It is the duty of a company duly chartered to furnish electric energy for domestic consumption within a reasonable time after due application and compliance with its proper regulations to extend its lines and furnish service, failing which it is liable to the applicant for the proximate pecuniary loss thereby caused, the Supreme Court of Alabama held, in Birmingham Railway, Light & Power Company versus Littleton (77 S.S. 65). If an electric service company, after due application and compliance with regulations, fails to extend lines and render service, the prospective customer is entitled to have considered as an element of damage the inconvenience and annoyance to which he was subjected by being denied the service. In action by an applicant for electric service arising for a company's failure to extend its lines, the certificate of the city electrician was competent evidence to show that plaintiff had complied with his obligation to make ready his premises for the use of electricity. Applicant for electric service to whom service was denied may recover cost of wiring his dwelling. Public service corporations are obliged to treat fairly and without discrimination all members of the community which they serve. The duty of public service corporations to serve the public fairly and without discrimination exists independently of statute and is independent of contract with a municipality or an individual. An electric power and light company is not bound to furnish energy to an applicant in the absence of performance by him of conditions precedent which it may establish, such as tendering prepayment for service. To entitle an applicant to receive electric energy from a public service corporation he must ask service at a proper time and place, in proper form and in proper manner.

Associations and Societies

The Directory of Electrical Associations, which is regularly printed in the first issue of each month, appears on page 755 of this number.

A. I. E. E., Denver Section.—The work of the Bureau of Standards will be discussed at the Denver meeting of the American Institute of Electrical Engineers on April 16.

San Francisco Electrical Development League.—At the March 20 meeting of the league Dr. Charles Cestre, University of Bordeaux, France, told of "Social and Economic Effects of the War on France."

A. I. E. E., Ithaca Section.—Some practical hints on illumination design were presented by Prof. F. K. Richtmyer on March 29 before the Ithaca Section of the American Institute of Electrical Engineers.

Electrical League of Cleveland.—Prof. H. E. Bourne of the Western Research University addressed the Electrical League of Cleveland on Thursday, March 28, on the subject of "Some Consequences of the Collapse of Russia."

American Association of Engineers, New York Chapter.—Garrett P. Serviss will address the New York Chapter of the American Association of Engineers on "The Glory of the Engineer" on Wednesday, April 10, at the Hotel McAlpin.

American Society of Heating and Ventilating Engineers.—"Fuel Conservation" will be the subject of discussion of the American Society of Heating and Ventilating Engineers on April 15 at the Engineering Societies Building in New York.

A. I. E. E., Chicago Section.—A joint meeting of the Western Society of Engineers and the Chicago Section of the American Institute of Electrical Engineers was held March 25 in Chicago. Charles S. Burgess gave an interesting talk on "Some Possibilities in Electrochemical Industry."

Engineering Societies of St. Louis.—J. A. L. Waddell, consulting engineer of Kansas City and New York, delivered an address entitled "The Engineering Profession Fifty Years Hence" at a meeting of the Collimation Club, at which the Associated Engineering Societies of St. Louis were guests.

American Association of Engineers.—The fourth annual convention of the American Association of Engineers will be held at Chicago on May 14 for the election of officers for the ensuing year. The present officers of the association are: Edmund T. Perkins, president; W. H. Finley, first vice-president; Isham Randolph, second vice-president; A. H. Krom, secretary; E. B. Miller, assistant secretary, and John Ericson, treasurer.

Electrical Conference of Philadelphia.—W. J. Canada of the International Shipbuilding Corporation, formerly of the Bureau of Standards, spoke on "The National Electrical Safety Code" before the electrical conference of Philadelphia on March 22.

Buffalo Engineering Society, A. S. M. E. Section.—"Water Power on the Pacific Coast" was the subject of an address given by Prof. D. S. Kimball, University of Cornell, before the American Society of Mechanical Engineers section of the Engineering Society of Buffalo.

Association of Iron and Steel Electrical Engineers, Philadelphia Section.—"Electricity as Used in Modern Shipyards" is the title of a paper to be presented to-day by C. M. Hensen, chief electrician of the shipbuilding plant of the Bethlehem Steel Company, Sparrows Point, Md., before the Philadelphia Section of the Association of Iron and Steel Electrical Engineers.

American Society of Mechanical Engineers, New York Section.—On April 9 there are to be joint afternoon and evening meetings of the Metropolitan student branches and the New York Section of the American Society of Mechanical Engineers. There will be short addresses by the prominent speakers in all branches of engineering on how engineers are helping to win the war on land and sea and in the air.

A. S. M. E. Spring Meeting.—"Fuel Economy" will be the important subject for discussion at the spring meeting of the American Society of Mechanical Engineers, which was announced previously in the March 23 issue of the ELECTRICAL WORLD. Topics upon which discussion is solicited are as follows: What are the economic effects of impurities in coal? To what extent is fuel oil likely to be used as a substitute for coal? How can soft coal be burned without smoke in marine boilers? What are the possibilities in the direction of the utilization of anthracite wastes? What instruments are useful and desirable in the boiler room as aids in saving coal? What is essential to the economical operation of hand-fired boiler furnaces when using soft coal? To what kinds of plants and coals are the different types of mechanical stokers respectively adapted, and what is the limiting factor to their use in the small plants? What experience have you had in the use of wood as fuel? To what extent is wood available as fuel? What coal economies can be effected in residence heating? What coal economies can be effected in small steam plants? What experiences have you had with the storage of coal? While the above topics are all that can be suggested for discussion, additional short papers on any fuel topic are desired for publication. Items of interest on fuel performance should be sent to the secretary of the association. The meeting will be on Thursday morning, June 6, at the Worcester Polytechnic Institute at Worcester, Mass.

Commission Rulings

Important decisions of various state bodies involving or affecting electric light and power utilities.

Village Franchise Not Controlling.—The New York Public Service Commission, Second District, answering a complaint of trustees of South Glens Falls against the United Gas, Electric Light & Fuel Company of Sandy Hill and Fort Edward on gas rates, holds that the condition in the franchise granted by the village is not controlling so as to prevent the commission from authorizing an increase in the rate in the event that the company can justify such increase on the ground that it is failing to earn a fair return upon the value of its property employed in the public service. It appearing from the record in this case that the complainants do not propose to contest the increased rate if the decision is adverse to them, the complaint is dismissed.

Rate Increases in Illinois.—The Illinois Public Utilities Commission has acted on a large number of petitions for increases in electric rates, in some cases allowing the increased rates and in others postponing final decision until more complete and detailed investigation could be made. Among the companies allowed to make increases were the Illinois Northern Utilities Company of Dixon, affecting Amboy, Lee Center, Shaws, Sublette and Polo, effective March 20; the Southern Illinois Light & Power Company, affecting Raymond, Donnelson, Palmer and Troy, effective March 28; a 13 per cent increase of the Alton Gas & Electric Company, affecting Alton, and the Little York Electric Company, affecting that town only, dating from Feb. 21. Among the cases suspended was the petition filed by thirteen subsidiary companies of the Illinois Traction System, affecting a wide number of towns and cities in northern, central and southern Illinois, these increases being asked on electric light, gas, power and street railway service. This petition was suspended until July 28, 1918. Other suspensions included the Saline Electric Company, involving Duquoin and St. Johns, postponed until July 14, 1918, and the DeKalb-Sycamore Electric Company, affecting cities named, this petition being held in abeyance until July 28, 1918. A number of petitions for increases were also received by the commission. Among these were the petition of the Central Illinois Utilities Company, affecting Paxton and twenty-six other towns; the Rockford Electric Company, asking permission to increase lighting rates and also asking suspension of the rule of the commission which compels companies to pay for electric service extensions, this last request to be effective only for the period of the war.

Stephen C. Pohe has resigned as manager for the Electric Bond & Share Company of the Columbia & Montour Electric Company and the North Cumberland Gas & Electric Company at Bloomsburg, Pa., to become manager for H. B. Walbridge & Company, former owners of the Bloomsburg property, of the Penn Public Service Company at Clearfield, Pa. Mr. Pohe was born in 1885 and on graduation from the Potts Business College, in 1902, entered the office of the Berwick (Pa.) Light Company, in time becoming assistant to the manager and later, in 1907, manager. In 1909, when this company was merged into the Columbia

S. C. POHE

Power, Light & Railway Company at Bloomsburg, Mr. Pohe was made superintendent of new business, which position he held until 1910, when he was appointed general superintendent. In 1912 the Walbridge interests gained control of the gas and electric properties, which were reorganized under the name of the Columbia & Montour Electric Company, the railway properties being also reorganized, under the name of the North Branch Transit Company. Mr. Pohe became general manager for both companies. Mr. Pohe has been very active in association work in the state, having been elected president of the Pennsylvania Electric Association in 1915.

Charles H. Tenney, head of Charles H. Tenney & Company, public utility managers and engineers, Boston, has been commissioned lieutenant-colonel in the Ordnance Department of the United States Army and has been placed in charge of the financial department. Mr. Tenney was born at Everett, Mass., in 1868, and began his business career with N. W. Harris & Company, bankers, Boston and New York, later becoming a member of the firm of Thompson, Tenney & Crawford, bankers, with offices in New York. About fifteen years ago he went to Boston and began to build up the organization bearing his name, which has become one of the best-known and most highly reputed syndicates in the Eastern public utility field. His brother, Albert B. Tenney, vice-president of the company, is also active in war work.

Men of the Industry

Changes in Personnel
and Position—
Biographical Notes

H. A. Price has been appointed local manager for the Alabama Power Company at Jasper, Ala.

W. B. Emmert has been appointed a vice-president of the United Gas & Electric Engineering Corporation.

Wayne Warfield has been appointed lighting superintendent of the Savannah (Ga.) Electric Company, succeeding J. L. Alexander.

R. M. Obergfell, assistant electrical engineer at the Underwriters' Laboratories, Chicago, has entered the engineering division of the Signal Corps of the National Army.

Walter R. Moulton, illuminating engineer of the Consolidated Gas, Electric Light & Power Company of Baltimore, Md., who recently resigned, has joined the staff of the Robertson-Catact Electric Company of Buffalo as industrial lighting engineer.

H. M. Byllesby, president of H. M. Byllesby & Company, who has devoted his time to government service since November, 1917, as a major in the aviation section of the Signal Corps, in charge of national recruiting, has been commissioned lieutenant colonel in this service.

Clarence P. King, after an administration of more than six years, retired as president of the Washington (D. C.) Railway & Electric Company System, including the Potomac Electric Power Company, on March 21, and will make his headquarters in New York City for the present in order to give attention to personal interests.

B. W. Cowperthwait of Faribault, Minn., the president-elect of the Minnesota State Electrical Association, was born at Danbury, Conn., and received his early education in the schools of that city. Upon finishing school he entered the service of the Danbury & Bethel Gas & Electric Light Company. Leaving that position in 1901, he assumed the management of the Faribault (Minn.) Gas & Electric Company for C. A. Coffin, who was then owner of the property. In 1909 this company was purchased by H. M. Byllesby & Company and together with properties in adjoining towns was made the Consumers' Power Company. Later the name was changed to the Northern States Power Company, Mr. Cowperthwait being made manager of the Faribault division, comprising thirty-four communities. About a year ago, when the principal office of the Northern States Power Company was moved to Minneapolis, Mr. Cowperthwait was appointed assistant general manager, which position he still holds.

E. C. Deal has been appointed general manager of the Springfield Gas & Electric Company, and also general manager of the Springfield Traction Company, of Springfield, Mo. He is a Georgian by birth and gained his early experience with the lighting company of Atlanta, Ga., which he served in various capacities from 1894 to 1898, except for short periods when he was superintendent of the Light & Water Company at Brunswick, Ga., and engaged in special engineering work for the government in Key West during the Spanish-American War. He then entered the organization of Stone & Webster of Boston, where he filled dif-

E. C. DEAL

ferent positions of responsibility, resigning in 1894 to become connected with the Gas & Electric Company of Bergen County, New Jersey, as chief engineer in charge of the operation of the company's properties in more than forty municipalities in northern New Jersey. When that company was absorbed by the Public Service Corporation of New Jersey Mr. Deal became superintendent of the latter company's electric properties in central New Jersey. In 1908 he joined W. N. Coler & Company, New York, as manager and engineer of public service properties of theirs. On the reorganization of the Augusta-Aiken properties Mr. Deal was appointed the general manager of the Augusta-Aiken Railway & Electric Corporation, the successor company in Augusta. This was in April, 1911. In April, 1913, he was elected vice-president of the company in addition to general manager. He was also made vice-president and general manager of the Georgia-Carolina Power Company, controlled by the same interest. He resigned in 1914 to become connected again with W. N. Coler & Company as vice-president and general manager of properties. He resigned in 1917 in order to become the general manager of the Trinidad (Col.) Electric Transmission Railway & Gas Company, with which property he has been connected up to the present time. Mr. Deal is a past-president of the Southeastern Section of the N. E. L. A., also past fourth vice-president of the parent body.

TRADE & MARKET CONDITIONS

News of the Trade for the Manufacturer, Wholesaler and Jobber
of Electrical Equipment and Supplies—
Notes on Industrial Activities and Business Methods

TOTAL ELECTRICAL EXPORTS

FOR 1917 AMOUNT TO \$55,478,079

December Establishes a Record of \$5,726,376 for a
Single Month's Exports—Large Shipments
of Wire and Cable and Motors

Electrical exports for 1917 reached a total of \$55,478,079, the largest total ever registered in any twelve-month period. This figure was made possible by a number of record-

FIVE-YEAR GROWTH IN ELECTRICAL EXPORT TRADE

breaker months, the greatest of which was December last, when a total of \$5,726,376 worth of electrical goods was exported from the United States. As will be noticed from

Thus in 1917 the exports were a little short of twice those of 1913, which was supposed to be the best export year for electrical goods prior to the war. To what extent the exports of electrical goods have grown in value in the last five years is shown in the accompanying curve. As will be noted, in 1914, owing to the war in the last half of the year, exports fell off considerably. They picked up a bit in 1915, owing to the increase in industrial activities the latter part of the year, and from then on forged rapidly ahead until the record total of 1917 was reached.

The Baby Bond—The Man's Choice

AIDING CONSERVATION IN SUPPLY JOBBING HOUSES

Discussion of Means for Eliminating Waste in Jobbing Organizations as They Exist and Operate To-day

A Middle Western jobber concluded after a study of several jobbing houses in his neighborhood that the average electrical jobbing house has two very apparent failings—first, too much red tape; second, inefficient clerks. In a paper before a recent convention this jobber cited instances to substantiate his conclusions. Some of these instances follow:

One company which has an elaborate system of handling orders is so far behind in maintaining the system as to render one of the prime objects of the system worthless. Another has elaborate files containing many copies of the same information. Another concern does not segregate its filing by months or years, but leaves dead filing to become mixed with that of recent date. Yet another firm has changed its system of accounting three times in two years and has changed its arrangement of information from towns in its territory from an arrangement by towns to an alphabetical arrangement, then to a classification by states, then to a numerical system. Another jobber spends \$3,120 a year wastefully entering invoices from manufacturers on a manufacturer's ledger accounts and rendering state-

DETAILED FIGURES OF EXPORTS OF ELECTRICAL MERCHANDISE

Articles Exported	December		Twelve Months Ended		December
	1916	1917	1915	1916	1917
Batteries	\$212,457	\$370,486	\$1,364,999	\$2,025,250	\$3,624,222
Carbons	178,567	178,567	178,567	178,567	736,717
Dynamos or generators	305,759	138,450	1,872,191	1,867,565	2,356,780
Fans	23,422	73,106	374,649	313,771	622,731
Heating and cooking apparatus	58,701	58,701	58,701	58,701	256,533
Insulated wire and cables	630,732	676,651	2,761,609	4,943,577	7,187,951
Interior wiring supplies, including fixtures	110,750	134,398	882,891	901,657	1,405,772
Arc lamps	1,146	1,534	23,983	15,467	16,418
Carbon-filament lamps	16,297	27,172	158,815	124,776	187,876
Metal-filament lamps	128,394	341,086	865,188	1,420,309	2,884,675
Magnetos, spark plugs, etc.	328,527	328,527	328,527	328,527	1,757,848
Meters and measuring instruments	102,832	191,539	657,129	884,241	1,213,278
Motors	526,952	730,585	3,278,413	4,932,831	6,484,972
Rheostats and controllers	21,641	21,641	21,641	21,641	93,612
Switches and accessories	221,022	221,022	221,022	221,022	1,025,003
Telegraph apparatus, including wireless	15,654	44,644	136,890	209,343	555,703
Telephones	301,107	278,162	910,623	1,813,969	2,212,237
Transformers	86,370	213,243	737,680	1,051,168	1,747,884
All other	2,284,965	1,696,862	10,316,528	19,740,151	21,107,867
Total	\$4,746,837	\$5,726,376	\$24,341,588	\$40,244,075	\$55,478,079

the accompanying table, the exports of motors and insulating wire and cable for last December were particularly large because of the activity in troop movements:

The year of 1917 compares with previous years as follows:

1917	\$55,478,079	1914	\$19,963,115
1916	40,244,075	1913	28,197,363
1915	24,341,588		

ments of its monthly and annual purchases. Still another jobber spends over \$2,400 a year in wages for extra help who make journal entries of business before posting the ledger.

Such concerns have too much system. Others have not enough. For instance, one concern permits orders to be

taken over the telephone, a single memorandum going to the shipping room without any registration or number. If it is lost, the merchandise is not paid for. Simplicity and accuracy should be the features of any system for handling business, with consideration for expanding the system with growth of business. The business of one concern with such a system has grown from \$50,000 a year to \$1,000,000 a year, without necessitating a change in the system.

A Bond for Freedom's Cause

GOVERNMENT PRACTICES

IN PURCHASING SUPPLIES

The Delivery, Packing and Wire-Reel Charges Formerly Customary Are Not Acceptable to the Buying Officials

Jobbing houses are busier now than ever before, government and industrial demands making almost the entire market. Government demand is particularly heavy and exacting. When the government wants anything it is for immediate delivery. Frequently the orders clean out the stock on hand or else reduce it far below a working amount.

In addition, the government in asking for quotations is not inclined to follow trade practices that have prevailed for years, but rather imposes its own standards. Thus the government in buying wire will not pay an extra charge for reels. The practice has been for the buyer actually to make a deposit on all reels, to be returned on the return of the reel. These reels are by no means an inconsiderable element in the cost of a reel of wire.

Also, the government refuses to pay packing charges as such. This is an item of cost that has generally been considered an extra.

In addition, the government does not pay delivery charges. For that reason all quotations must necessarily be f.o.b. point of delivery instead of shipping point. When the frequency with which shipments must be made by truck is considered, it can be appreciated that this is no small item.

METAL MARKET SITUATION

Prices on Iron and Steel Products Continued by an Official Order—Copper Deliveries Slow

Very little if any change has occurred in copper. There seems to be an ample supply of the metal available to meet and satisfy the requirements of the industrial manufacturer, but it is being released very cautiously by the committee in charge. The jobbing lot price is being slightly shaded. Deliveries are still back, and freight conditions have not bettered appreciably. The decision of the President continuing the present scale of prices for iron and steel products for another three months from March 31 has been announced. The only change is on basic pig iron and heavy melting steel scrap, which was reduced \$1. Tin is in no better supply, with prices nominal but exceedingly high. Old metals remain practically unchanged.

NEW YORK METAL MARKET PRICES

	March 25			April 1		
	£	s	d	£	s	d

Zinc, old scrap	5.25	to 5.75	5.00	to 5.62½

*Nominal.

THE WEEK

IN TRADE

ACCOUNTS received from various sources indicate that the electrical industry is enjoying a period of unusual activity. Sales of equipment and material in increasing quantities, chiefly for government war activities, directly and indirectly, are keeping stocks of staples at a comparatively low stage. The demand for house-wiring devices of all kinds is heavy. Poles and pole-line material are moving briskly. Motors of various sizes, new and second-hand, large transformers, switching apparatus, etc., are reported as enjoying a strong sale. Jobbers are stocking up liberally with electric fans in anticipation of an active season.

Deliveries are weak and uncertain, both freight and express. In some sections labor is scarce and the demand for skilled workmen is far beyond the supply.

Collections are improving with manufacturers, jobbers and dealers, and payments are being promptly net. Credits continue to receive careful attention.

NEW YORK

Jobbers are very busy. Most of them are selling merchandise for government requirements, which, together with industrial work, compose almost the entire market. Building operations are down to practically nothing. Jobbers are having difficulty in obtaining labor as well as stocks. Almost no local houses have complete stocks. Wire and conduit especially are in uncertain supply.

Where license certificates can be obtained from the traffic committee the export trade is excellent, but for lack of tonnage the refusals are more plentiful than those favorably acted upon. Locally collections are reported as making a good showing; in fact, are said to be in the main prompt.

PORCELAIN.—The demand is strong, with deliveries the chief obstacle. Shipments are being made by express where possible, but they are not always dependable. The new price list said to be on the way had not appeared by April 1.

SOCKETS.—An unusually brisk call for export is reported in sockets. The kind of goods called for is not familiar to the trade here, presenting peculiar sizes and models.

POLES.—Sizes of about 35 ft., the popular length, of chestnut are difficult to obtain. The demand is steady. Shipments are checked by embargoes. Power houses and central stations are in the market for their spring requirements in replacement and maintenance work.

CONDUIT.—Stock is still short, government work taking about all the available pipe in sight for industrial plants. Deliveries remain backward, the mills having shipments detained for lack of cars.

COLLECTIONS AND CREDITS.—Collections in this territory are reported as quite satisfactory. The Moral Risk Club, which held its meeting last Friday, considered conditions favorable. Credits, however, are dealt with firmly.

FUSES.—Refillable fuses are reported to be in brisk demand, according to leading jobbers. On inclosed fuses a shorter discount was announced by a large distributor.

HEATING APPLIANCES.—With the active sales campaigns now being carried on by manufacturers, distributors and jobbers, sales of these goods are expanding rapidly. Toasters, electric irons, grills, pads, percolators, chafing dishes, etc., are receiving special attention in the large department stores, and dealers are also "doing their bit" to boost trade, with commensurate results.

SWITCH BOXES.—A leading distributor recently increased his discounts sharply on sectional conduit switch boxes. Black, that had ruled net for a long time, is now

quoted at 40 per cent off on the \$2 list; \$2 to \$10 list, before 20 per cent, is now 50 per cent off; \$10 to \$50 list, formerly 30 per cent, is now 64 per cent off. For galvanized the discounts are now 30 per cent, 40 per cent and 52 per cent off, as against net, 5 per cent and 15 per cent.

CHICAGO

The trade is continuing in good volume, with little change in the condition of stocks. Central stations are buying very little, and some jobbers see little chance of business opening up in this line. Industrial plants, however, are active and give promise of becoming more so. The word that more government business is to be shifted to the Chicago district is hopefully received and is believed, since there appears every good reason for following such a course and no good reason for not doing so. As yet the railroads have not opened up very strongly on buying. That there will shortly be a change here is expected. So while the market continues spotty there appears no reason to complain about present volume and every reason to expect increases. What is true in the jobbing field holds also for the manufacturers' agents and smaller manufacturers. Many of these report 1918 business well ahead of the same period for 1917 in point of gross sales.

It is possible that there may be a change in the buying methods in connection with material used for the city of Chicago. The city electrical department has been attacked by the politicians, and threats are made to reduce its strength to one lone man and to do all city electrical work by contract. This may never get further than talk, however. The contractor-dealer movement for better merchandising is gaining headway, as is evidenced by the fact that more than 100 concerns have actually joined the Illinois association and about 75 paid members have been secured in Wisconsin. Central-station support of the plan is gaining.

Building activities continue to gain. The number of building permits issued in the week ending March 22 was 672, as against 767 for the same week last year.

PINS AND BRACKETS.—An advance of about 10 per cent on pins and brackets has been scheduled. Shortage of material is given as the cause for the increase.

VACUUM CLEANERS.—Dealers report that the greatly increased price of brooms is making for a much better cleaner market. Brooms which formerly cost 25 cents are now quoted at \$1 to \$1.50 each.

BELL-RINGING TRANSFORMERS.—In spite of curtailed building activities manufacturers are showing a good volume.

WIRING ACCESSORIES.—Lock nuts, toggle bolts and sundry metal accessories of the same sort, which are used in wiring, are reported not to be moving rapidly. Some of the Chicago jobbers have very large stocks on hand. One concern is reported to have in its warehouses more than 1,000,000 lock nuts.

BOSTON

The volume of trade continues heavy, especially in industrial lines related to government needs, and there is, of course, no let-up in direct war orders. There are minor fluctuations among jobbers with respect to orders, but on the whole the industry is very active. Collections are fairly good, and in some cases payments are being made within ten days of delivery from the jobber's stockroom. More punctual train service on the railroads is now being enjoyed, and this has a far-reaching effect on the efficient transaction of business in all lines. Sporadic house-wiring contracts are being handled by contractors. Throughout the industry active preparations are being made to insure the success of the third Liberty loan. Uncle Sam's needs come first, and new enterprises are at a low ebb. Labor is exceedingly scarce, and the demand for skilled workmen for industrial plants is far beyond the supply.

Governmental assistance announced recently in connection with the financing of the New York, New Haven & Hartford Railroad appears certain to improve the business outlook

in New England, and the electrical industry naturally will share in better conditions on this important property. The retail trade appears to be in a healthy condition, and a large volume of summer business is expected by central stations in touch with shore and interior vacation resorts, both in the sale of energy and through appliance merchandising.

FANS.—Jobbers are stocking up well in anticipation of a substantial summer business. Although the returns depend in large degree upon the weather from year to year, last year's fan shortage made such an impression locally that there is a decided disposition not to be caught short again. One jobber, for instance, sold 200 fans of a single make last year and will start the present season with a stock of 400.

TRANSFORMERS.—Central-station power engineers are anxious about the long deliveries now being quoted on power transformers. In some cases it has been found expedient to rearrange the locations of transformers on factory service, grouping different establishments together in an effort to cut down idle capacity and to offset the long delays necessary in getting new equipment. Recent quotations run up close to a year on units of 100 kw. and over.

LAMPS.—Manufacturers are now finding it possible to stock up somewhat at the factories. The supply of glass is on a better basis than at this time last year. Comparatively little night work is being handled at present in a large New England plant which confines itself to above-miniature sizes. Easier conditions should prevail for the next few months.

SECOND-HAND MOTORS.—Trade is very brisk, and dealers report a scarcity in the larger sizes. Up to and including 10 hp. motors are fairly plentiful. The larger motors sell for practically as much second-hand as new, so great is the demand. Inquiries for motors are very responsive to the publication of news relative to government contract distributions.

SWITCHES AND ALLIED EQUIPMENT.—An enormous demand exists for switching apparatus, and the accumulation of factory stocks seems practically out of the question at present. The high cost and shortage of labor is probably the most serious factor in handling this class of production at present. Raw materials are becoming more plentiful and one manufacturer is buying steel plate for switch-box use on five weeks' delivery, carload shipment. Reduced prices on both steel and copper are now being obtained. Central stations are heavy switch buyers for motor installation work. Price advances of two months ago do not appear to have cut down orders much if any.

STORAGE BATTERIES.—Deliveries are improving somewhat, owing to enlarged factory accommodations. Prices are firm and government business predominates.

ATLANTA

There is little change to record for this week. All lines seem to be strong, with the exception of a few items that have shown a tendency to slow up. The development of water powers for nitrate production is the main topic of conversation, indicating that the government has other projects in view besides the Muscle Shoals development. The preliminary expenditures for this plant have been definitely decided upon, to be made up as follows: \$5,000,000 for synthetic-process nitrate plant, \$20,000,000 for hydro electric plant, \$30,000,000 for cyanamide nitrogen fixation plant. A new five-million-dollar plant is contemplated for Kingsport, Tenn. The product to be manufactured is not for publication at this time. The White-Park Mitts Company, Concord, S. C., has been incorporated for \$2,000,000 for the manufacture of cotton cloth.

With the exception of a few lines it is apparent that factory conditions are much better and stocks show slight gains. Although this state of things is conducive to better promises of shipments, this section has not been able to feel its effect or to reap any benefits, especially where embargoes and transportation conditions work in adverse ratio, offsetting any direct advantage that might have been attained.

CREDITS AND COLLECTIONS.—Collections have slightly improved within the last few weeks. There is no doubt that more pressure is being brought to bear along the

entire field, with a corresponding stiffening in credits and extensions. The trade acceptance is looked upon with more favor of late by the jobbers, but a few of the manufacturers are taking an ultra-conservative view of the situation, apparently awaiting the trend of conditions.

MOTORS.—The direct sale of fractional horsepower types has been limited in this section, owing to the fact that they are usually shipped with machinery they are meant to operate. Manufacturers report that shipments are improving on direct-to-consumer sales. There is no cessation in the demand for motors up to 10 hp., but the trouble is to get them shipped. Factory stocks are accumulating, while local stocks are becoming depleted. Orders for capacities up to 75 hp. are coming in briskly, but shipments are the same as with the smaller ratings. Sales in the larger ratings up to 100 hp. always show stimulation at this season of the year, owing to anticipated requirements for seasonal industries, such as oil mills, cotton gins, fertilizer plants, etc. Factory conditions show considerable improvement, as evidenced by better shipment promises, the only deterrent factor being poor freight movements. Prices have been steady and no change is expected soon.

METERS.—The slowing up of building operations is reflected in the demand for residence-type watt-hour meters, which shows a slight decline during the last few weeks. Stocks are in good shape and very well distributed throughout the Southeast. Factory shipments are improving. Activity continues in the polyphase type.

FANS.—A big business is expected during the coming season. Ceiling fans are especially active at this time, owing to government requirements for hospitals and mess halls at the various cantonments. Jobbers have placed substantial orders.

SEATTLE

The volume of business transacted by both jobbers and retailers continues very heavy, war industries dominating trade, although home building continues to increase, augmenting the sales of house-wiring devices. The feature of the last week's business was the award of a contract by the United States Shipping Board for miscellaneous electrical supplies for government work in Aberdeen and a heavy movement of power apparatus, including large-size motors and generators. Sales of flood-lighting outfits over the past several weeks show a decided increase. The movement of washing and sewing machines, particularly the latter, is very brisk. Stocks of domestic appliances have been replenished and are in fair condition. The recent arrival of several cars of conduit served to relieve the strained condition temporarily.

Sales to Seattle and Tacoma shipyards are heavy, but no particular increase over last week is noted. Business with yards in the Gray's Harbor and Portland territory shows a heavy increase, especially in Portland. An Astoria (Ore.) firm has secured contracts for installing machinery and fully equipping all government vessels constructed in the lower Columbia River district, numbering more than thirty. To care for the work the concern is erecting additional shops and housing accommodations for employees. Two-way wooden shipbuilding plants started in Everett will shortly be enlarged to six ways. A prominent Northwest contracting firm plans a concrete shipbuilding plant. A site at Vancouver, Wash., is said to be favored. The Pioneer shipbuilding and repair plant near Seattle, which has changed ownership, will be enlarged immediately, and considerable heavy electrical equipment is to be purchased.

Government buying for cantonment work shows some increase over last week. Credit managers in the Puget Sound district report March an exceptionally healthy month as regards business placed and collections, collections becoming easier as the year progresses. Money is very free. During the month a large amount of new business was received from old customers and a considerable number of new credits were placed. New war industrial plants under formation appear to have a stable backing. Government collections are prompt.

Prospective builders are being warned that in the very near future the prices of many building materials will be

advanced decisively. The home building campaign in the Sound cities is increasing. During March in Seattle permits for buildings valued at approximately \$1,000,000 were issued, as compared with slightly more than \$500,000 in March of last year. The ratio in Tacoma is nearly as large. The immediate expenditure of \$1,000,000 for buildings at Camp Lewis is authorized by the government, and ground was broken at Vancouver, Wash., for ten additional barracks. The steel shipyard in Tacoma was awarded the contract by the United States Emergency Fleet Corporation for ten steel ships of 7500 tons, in addition to three now under construction.

The lumber industry of the Northwest is imperiled by the grave car shortage, which is daily growing more acute. Efforts are being launched by government officials to break the embarrassing situation. The labor situation in cities as well as in farming areas is daily becoming more acute. The United States government employment office in Seattle reports a desperate shortage in common labor in strictly war industries. The wheat farmers east of the mountains are incessantly calling for help, and the situation is serious.

SAN FRANCISCO

This has been a busy week for the electrical industry. Shipments have been good. Once again it is possible to accumulate shelf stock as a reserve, and the fine warm weather that followed another welcome rainfall has added the last touch of optimism for the future—an optimism which even the news of the great German offensive failed to diminish. This past week Libby, McNeil & Libby let contracts for workmen's cottages at their Selma (Cal.) and North Yakima (Wash.) plants. It now appears that, as the result of an investigation by a member of the industrial commission of the National Council of Defense, from 2000 to 5000 houses for workingmen in the San Francisco Bay district are recommended for immediate construction, and a representative has left for Washington to secure the necessary federal authority for priority of attention.

STREET ELECTROLIERS.—Several communities are planning better lighting of their streets, in some cases for better protection and in others as a portion of a general scheme for greater civic beauty. In one week Alpaugh and Fresno, in the San Joaquin valley, and Santa Barbara and Los Angeles, in southern California, reported that plans and specifications for such work had been submitted to their respective city councils.

POLES.—Pole business is in a most abnormal and unsettled state, suffering from the rather unusual combination of slack demand and difficult deliveries. This situation may be explained by the shortage of available power and the present high cost of construction material. On the other hand, the pole yards are situated in the Pacific Northwest, where a great deal of government lumber is requisitioned. Cars and boats are difficult to get and labor is almost impossible to secure, and then only at high wages. One of the large pole companies states that when it is fortunate enough to secure a boat for deliveries along the Pacific Coast it is customary to load it with everything available, instead of proportioned stocks, and thus pole stocks are poorly distributed.

CROSS-ARMS.—Cross-arms, of course, are affected by the conditions noted above, with the addition that the forests in which they are cut contain lumber that is valuable for governmental purposes and demands the attention of all available labor, making slow deliveries.

POLE-LINE HARDWARE.—Hardware is a necessary link in pole-link construction, and its present sale is slack, though there is a certain amount of construction on industrial plants and mines that lie in new districts and are engaged in war service.

SCHEDULE MATERIAL.—Orders for switches, sockets, rosettes, cut-outs and other house-wiring material are heavy and surprisingly numerous, considering the big decrease in reported jobs. Local representatives of large Eastern manufacturers assign this demand to the arrival of stocks ordered last year. Porcelain sockets and receptacles are wanted for factory wiring, and each new shipment is largely sold out before its arrival.

Current Prices of Electrical Supplies

New York and Chicago Quotations

THE prices quoted are those prevailing in standard packages of specified lots on apparatus and appliances in Eastern and Middle West markets at the beginning of business on Monday of this week. They are in all cases the net prices or prices subject to discounts from standard lists of contractors, central stations, dealers and others engaged in the resale of such goods.

Prices in Southern and other nearby markets will rule about the same as those in the Middle West, although slight modifications to cover increased freight and local demands should be expected. In the Far West and on the Pacific Coast the prevailing prices are naturally higher, covering as they must increased

freight and the necessity of larger stocks with increased interest and warehouse charges on account of the distances from sources of supply, infrequent turnover of stock and uncertainty as to delivery of goods in transit. Moreover, the Far West presents a wide variation in demand due to a small population spread over a wide area in agricultural and mining communities, as contrasted with the denser population of the East and Middle West, their nearness to the sources of supply, the more frequent turnover in stocks and the constant demands which arise in industrial centers. Price variations may be due to difference in grade of products of different manufacturers, to local conditions, or to both.

NEW APPARATUS & APPLIANCES

A Record of Latest Developments and Improvements in Manufacturers' Products Used in the Electrical Field

Outdoor Meter Boxes

An outdoor meter box which can be conveniently located where it can be read at any time without disturbing the consumer is being placed upon the market by the Safety Meter Box Company, 112 Hamilton Avenue, Cleveland, Ohio. It is claimed that the fire hazard of meters and fuses is greatly lessened by the use of this meter box because the box is of heavy metal which entirely incloses the meter. Another feature of the "Safety" meter box is the ease with which the meter can be installed or removed by the central station.

Multi-Stage Pump with Two Discharge Nozzles

The accompanying cross-section shows a multi-stage pump that has been developed recently by the Alberger Pump & Condenser Company, 140 Cedar Street, New York City. It is known as the Type "N" pump and differs from previous units manufactured by the same company in that the parts are more standardized. The shaft diameter of the two bearings is the same, thus permitting the customer to carry one bearing shell in stock to guard against accidents. The pump is hydraulically balanced to prevent end thrust, so no thrust bearings are required.

Leakage between the pressure and suction chambers is avoided by clearance rings placed between the rotating and stationary parts. There are two discharge nozzles, either of which may be used, as one of the openings can be closed by a blind flange supplied with the pump. The casing is of annular

CROSS-SECTIONAL VIEW OF MULTI-STAGE PUMP

form divided along the horizontal center line so that the upper part can be removed readily without disturbing the pipe connections. The suction and discharge openings are cast integral with the lower parts. The impellers are of bronze of the inclosed type with single side-entrance opening. The pumps ordinarily are furnished with bronze fittings, but special material may be or-

dered for unusual requirements. The multi-stage pumps can be driven by a belt, electric motor or steam turbine.

Semi-Indirect Lighting Fixture

The Panama Electric Lamp Company of Chicago and San Francisco is now marketing a lighting fixture of the design shown herewith. The lower bowl is of white translucent glass and the upper reflector is of white satin-finished porcelain. The unit is made in three standard sizes, which range from 14 in. to 19 in. (35 cm. to 48 cm.) in width at the ceiling flange. They are made for mounting with the ceiling flange against the ceiling or with the unit suspended at the end of a single-chain or three-chain support.

The manufacturer points out that the unit is notable for its simplicity and small number of parts. The socket and supports are concealed inside the reflector. The saddle or upper support

SOCKETS AND SUPPORTS CONCEALED
INSIDE OF THE REFLECTOR

can be attached to any size or type of outlet box. The bowl is ventilated at the bottom. Tests which have been made by the manufacturer indicate that one 200-watt gas-filled lamp in a "Panama-Lite" fixture will give a uniformly diffused downward intensity averaging more than 265 cp. over an arc of 110 deg. Special units of the same type are equipped with daylight glass.

Automatic Reclosing Circuit Breaker with Low-Voltage Lock-Out

The illustration which is printed herewith represents the wiring diagram of a type CN 400-amp. automatic-reclosing circuit breaker developed by the Automatic Reclosing Circuit Breaker Company, Columbus, Ohio. The switch has a low-voltage lock-out. When the breaker is opened either by an overload

or failure of voltage, the cut-out contact is held open by the main contact brush. In this position of the cut-out contact the circuit of the operating coil for reclosing can be closed only by the closing of the auxiliary contact arm. The auxiliary contact arm is closed by

AUXILIARY CONTACT ARM CLOSED BY TRIP
COIL WHEN CONDITIONS ARE NORMAL

the trip coil whenever load conditions are normal and the potential is restored to 50 per cent or more of normal value. The trip coil holds the auxiliary contact closed until the breaker has closed far enough to allow cut-out contact to assume normal position and the circuit of the trip coil to be opened by the dash-pot contact arm.

Air Pump with No Moving Parts

The C. H. Wheeler Manufacturing Company, Eighteenth Street and Lehigh Avenue, Philadelphia, has designed a "Radojet" air pump for high-vacuum condensers. The air pump operates on the dry-air principle. It has no moving parts and does not require lubrication or attention during operation. Other advantages may be summarized as follows: Low steam consumption, extreme simplicity, requires minimum space, no foundations and operates noiselessly. It starts quickly and gives continuous service with safety in operation. The principal characteristic of the "Radojet" is the use of steam jets for the removal of air. The "Radojet," as shown in the cross-section reproduced herewith, consists of two steam ejectors working in series, the upper ejector called the first stage and the lower the second stage.

Live steam is delivered to the first stage through opening L to pipe 2, auxiliary steam valve 3, expansion nozzles 5, across suction chamber 6, which is in communication with the condenser through the suction opening S. The steam expands in the nozzles, leaving with a very high velocity, and while passing across suction chamber 6 en-

trains the air and vapors to be compressed.

The mixture passes into the diffuser 7, from which it is discharged at higher absolute pressure than that of the air entering at *S* into a double passage 8 communicating with the suction chambers 9 of the second stage. These two suction chambers 9 are annular, giving

SECTIONAL VIEW OF AIR PUMP SHOWING PATH OF STEAM AND AIR

the commingled fluid a large entrainment surface.

Steam is simultaneously delivered through the strainer 1 into passage 10, which communicates with the annular expansion nozzle formed between two circular disks 11 and 12. The separation of these disks can be changed by adjusting screw 13 which changes the expansion ratio of the steam. The steam delivered radially by the annular nozzle 11 and 12 expands, leaving it as a jet at high velocity in the form of a sheet. In passing across the suction chambers 9 it entrains the commingled air and steam coming from the first stage and carries them into the annular diffuser 14, thereby compressing the mixture to atmospheric pressure and discharging it into casing 15, which is connected to the discharge opening *D*.

Another advantage of the air pump is that the steam contained in the mixture is condensed and the heat transmitted to the boiler-feed water, thereby raising the temperature. The air frees itself from the rising water and escapes through a vent to the atmosphere. The "Radojet" air pump can be used for surface, jet or barometric condensers. When it is used with the surface condensers it is found advisable to use separate pumps to handle the air and condensate. The condensate can be removed at approximately the exhaust steam temperature, while at the same time the dry-air pump would handle the air and vapors under the volume and temperature conditions imposed by the temperature of the circulating water. The use of this air pump with a jet condenser is advantageous because it is independent of the removal pump.

This makes it possible to vary the speed of the removal pump within a large range according to the variations of the discharge heads, thereby obtaining the most economical results.

Double-Dial Illuminated Pressure Gage

The Ashton Valve Company of 161 First Street, Cambridge "C," Boston, has placed upon the market a master-pilot pressure gage for use in large boiler and engine room installations. The gage, shown in the accompanying illustration, has a limited-pressure scale suitable for the ordinary range of working pressures. It is made with a special operating mechanism which will not turn the pointer at pressures below the minimum dial graduation.

The advantage of this special form of gage is that finer graduations may be used and that the figures can be of considerably larger size. This enables the slightest variation of pressure to be quite noticeable and the reading of the gage to be readily observed. The gage is made with single-face or double-face,

MULTIPLE-TUBE CONSTRUCTION INCREASES FLEXIBILITY

plain or illuminated dials with the usual support brackets. The multiple-tube construction employed with this gage permits increased flexibility of operation and the greatest durability, the makers say.

A Connector That Requires No Soldering

The Columbia Metal Box Company, 228 East 144th Street, New York, has placed upon the market the "Notorch" solderless connector for use in lighting fixtures, small motor leads, conduit fittings, junction boxes and cleat wiring. Fixtures can be connected with the "Notorch" connector easily and quickly by removing or loosening the screws. It is not necessary to cut or shorten the outlet wires. The connector is especially adapted for use behind shallow plates or on ornamental wall brackets where there is little room for joints. It is claimed that this connector saves time in installation, per-

mits a quality job and eliminates the necessity of using a blow torch which blackens ceilings and floors and creates a fire hazard. The device has been approved by the National Board of Fire Underwriters for a rating of 17 amp. for fixture wiring and for motor leads up to a 4-hp. rating.

Arc Regulator

An arc regulator for motion-picture projectoscopes that fits on the rear of the lamp house is being manufactured by the Barlow Electric Specialties Company, Inc., of Yonkers, N. Y. The device is composed of a small box containing the arc-regulating mechanism, which consists primarily of a powerful spring held in check through a magnetically controlled brake. The coils of the magnets are connected with taps off of the main feed wires to the machine. The apparatus feeds the carbons so that any change in voltage at the arc will be immediately adjusted.

Washing Machine with Safety Wringer

The accompanying illustration shows a new electric washer that is made of all metal with the exception of the wringer frame and revolving cylinder. The revolving cylinder is built of 2-in. (5.1-cm.) wood staves spaced 0.25 in. (0.63 cm.) apart and perforated with 0.5-in. (1.3-cm.) holes, thus affording ample openings for the passage of the water through the clothes. The cylinder makes a complete revolution in one direction and then reverses. The wringer is provided with a safety release, which enables the operator to stop the rolls immediately. It is supported by an upright arm extending from one corner of the washer and can

SAFETY RELEASE ON WRINGER ALLOWS ROLL TO BE IMMEDIATELY STOPPED

be placed and locked in any position desired. The washing machine, which is driven by a 0.25-hp. Robbins & Myers splash-proof motor directly connected by a shaft, is made by Altorfer Brothers Company of Peoria, Ill.

Trade Notes

E. N. NOUSE is now manager of the Chicago Electric Lamp Company of 138 West Lake Street, Chicago, succeeding H. S. Kurtz.

L. K. COMSTOCK & COMPANY, contracting engineers of New York City, have changed their address from 30 Church Street to 21 East Fortieth Street.

THE DUQUESNE ELECTRIC & MANUFACTURING COMPANY, Pittsburgh, Pa., announces the opening of a branch office at 230 South La Salle Street, Chicago.

THE H. W. JOHNS-MANVILLE COMPANY of New York City states that its Memphis (Tenn.) office was removed March 31 to new quarters at 804 Exchange Place.

THE WESTERN ELECTRIC COMPANY is making a display of all the principal domestic appliances it manufactures at the Hotel Brunswick, Boston. This is open to the trade.

THE INTERNATIONAL RADIO-TELEGRAPH COMPANY is the new name of the International Signal Company. The executive office is in Pittsburgh, Pa., with the factory in Brooklyn, N. Y.

THE THOMAS WRIGLEY COMPANY, 416 South Dearborn Street, Chicago, has moved its office and plant to 504 South Sherman Street. The company manufactures toggle bolts and pipe hangers.

THE NATIONAL PLANNING BUREAU of Wilkes-Barre, Pa., has inaugurated a campaign in the interest of the building trades, architects and engineers by means of private seals to be used on mail matter.

THE FRANK H. STEHLY, JR., COMPANY is announced as the successor to the Pennsylvania Supply & Equipment Company, 421 Widener Building, Philadelphia. This change of firm name became effective April 1.

W. F. TRENARY, JR., has been named representative for the Harrison Safety Boiler Works of Philadelphia, to have headquarters in the Brown-Marx Building, Birmingham, Ala. Mr. Trenary succeeds W. R. Jennison.

THE HOTPOINT DIVISION of the Edison Electric Appliance Company, Inc., of Ontario, Cal., has sent out notice that henceforth all communications in connection with contract work should be addressed to the general office of the Hotpoint Division, 5660 West Taylor Street, Chicago.

W. O. DUNTLEY, president of the Chicago Pneumatic Tool Company of Chicago, announced his resignation March 29, to take place the same date. Mr. Duntley gave as a reason for his resignation a desire to be relieved of the work of actively managing the concern and to devote more time to private business.

THE VULCAN SOOT CLEANER SALES COMPANY of Chicago has transferred to Dubois, Pa., its general sales office, with G. L. Simonds in charge. This is only a change in location to bring the sales, factory and engineers in immediate touch, with the idea of giving better service to all; the personnel remains as before.

THE PERFECTION STORAGE BATTERY COMPANY, formerly the Dealers' Electric Lighting Company, 2909 Indiana Avenue, Chicago, will move on May 1 to its new plant at Fortieth Street and Rhodes Avenue. This company is developing a semi-automatic lighting plant. It also makes storage batteries for farm lighting sets.

THE MILLER-OWEN ELECTRIC COMPANY, INC., of Pittsburgh, Pa., dealer in used equipment, expects to enter its new warehouse about July 1. The building, which will be 250 ft. long by 40 ft. wide, is being constructed especially to house used electrical equipment. Provisions are being made among other things for an assembling and testing department.

SUPPLEMENT No. 5 to Official Express Classification No. 25, applying on express traffic covered by tariffs issued subject thereto, is now ready for distribution and becomes effective May 1. This refers to the marking requirements of packages, bundles, etc., and a copy may be had by applying to local express offices or F. G. Airy, 861 Broadway, New York City.

GEORGE E. SWETT, until recently in charge of the power and mining engineering department of the Seattle office of the General Electric Company, has resigned to become general manager of the Pacific Machine Shop & Manufacturing Company of Seattle. In his new work Mr. Swett will be engaged chiefly in carrying out contracts for providing mechanical and elec-

trical equipment for ships. Mr. Swett was for three years at the Schenectady works, then for some time at the San Francisco office of the General Electric Company, and for the past five years was in the Seattle office of the company.

Trade Publications

WASHING MACHINES.—The Crystal Washing Machine Company is distributing a circular describing its Crystal washing machine.

REAMERS.—The Cleveland Twist Drill Company of Cleveland, Ohio, is circulating a bulletin entitled "Better High-Speed Reaming" which tells the advantages of its reamers and how they are made.

ELECTRIC SPECIALTIES.—The W. A. Bonnell Company, New York City, has issued catalog No. 203A, on electrical specialties. The book is well illustrated and contains a price list of the various electric fittings.

PANELBOARDS.—"Residence Panelboards" is the title of bulletin No. 1E, issued by the Crouse-Hinds Company of Syracuse, N. Y., illustrating residence panels and parts. Actual installations of panels are shown.

LIGHTING FIXTURES.—The Panama Electric Lamp Company of Chicago and San Francisco has issued a booklet describing its new fixtures, which are known as "Panama-Lite." They are designed for illuminating interiors.

SAFETY METER BOX.—The Safety Meter Box Company, 112 Hamilton Avenue, Cleveland, Ohio, is circulating a folder showing the advantages in the use of its safety meter box, which is made to be installed on the outside of consumers' houses.

STORAGE BATTERIES.—Titan storage batteries for isolated plants are described in bulletin No. 24 of the General Lead Batteries Company, 1790 Broadway, New York City, which is being distributed. The booklet illustrates both the open-glass-jar and the steel-rubber-jar type of battery.

ROLLER CHAINS.—The Link-Belt Company, Chicago, is distributing a booklet that gives preliminary information on recent roller-chain developments. The bulletin is well illustrated, showing the dimensions and construction of the new chain and also various applications for engine, auto-truck and tractor drive.

INDUSTRIAL TRUCKS AND TRACTORS.—The Elwell-Parker Electric Company, Cleveland, Ohio, has issued catalog No. 177, illustrating its electric storage battery industrial truck and tractor system. The bulletin shows the electric trucks in use and their various applications. It illustrates the operation of the elevator truck, the crane truck, and tractors.

LIGHTNING ARRESTERS.—The Westinghouse Electric & Manufacturing Company of East Pittsburgh, Pa., has issued catalog 1A, dealing with lightning arresters. Lightning is discussed in the bulletin and facts are given about the causes and effects of lightning. Various installations and arrangements of lightning arresters and fittings are shown in outline drawings. Descriptions of choke coils are also presented in the bulletin.

SOOT BLOWERS.—The Diamond Power Specialty Company of Detroit, Mich., has issued bulletin 119, referring to soot blowers for water-tube boilers. The bulletin deals with the mechanical features of the soot blower and presents a discussion of the soot removal problem from the economical point of view. A detailed record of tests of fuel saving, including actual flue-gas temperatures, charts and ledger sheets, is also produced. The book is well illustrated, showing actual installations and charts of Venturi and straight nozzles.

LINE INSULATORS.—The R. Thomas & Sons Company, East Liverpool, Ohio, has recently issued catalog No. 16, showing its transmission-line insulators for all voltages. This bulletin is well illustrated and shows applications of the insulators and types of construction used on high-tension transmission lines. It includes line drawings of various insulators for power house and substation use, including suspension insulators and strain clamps. The bulletin is really a reference book because the dimensions and conditions under which the insulators will operate are given. Prices of insulators are also listed.

COUNTRY HOME LIGHTING.—The engineering department of the National Lamp Works, Nela Park, Cleveland, has recently published bulletin 34, which deals with country home lighting. A general discus-

sion dwells on the generating plant and wiring, stress being laid upon the fact that satisfactory operation depends greatly upon the wire being sufficiently large to carry the necessary power without an undesirable voltage drop. A table is produced which facilitates the selection of wire of the proper size. A short descriptive section is devoted to Mazda lamps for country home lighting, and photographs of actual installations are used to illustrate the lighting of the home.

New Incorporations

THE ECLIPSE ELECTRIC COMPANY of Canton, Ohio, has been incorporated with a capital stock of \$10,000 by Charles Miller and N. W. Worth.

THE HERTNER ELECTRIC COMPANY of Cleveland, Ohio, has been incorporated with a capital stock of \$100,000 by F. Treadway, Norton McGiffin, F. H. Peitz, William H. Marlatt and B. G. Morrison.

THE DETROIT (MICH.) ELECTRIC SALES COMPANY has been incorporated by Alton E. Archer, Joseph L. Freaser and Herman C. Wieland. The company is capitalized at \$20,000 and proposes to deal in gas and electric automobiles.

THE ELECTRICAL MAINTENANCE COMPANY of Wilmington, N. C., has been incorporated with a capital stock of \$10,000 by C. R. Siggs, M. C. McIntyre and J. Hobbs, Jr. The company proposes to do general electrical engineering business.

THE MUTUAL APPLIANCE COMPANY of Madison, Wis., has been chartered with a capital stock of \$50,000 by H. R. Marti, A. R. Earle and L. B. Martin, all of Edgerton, Wis. The company proposes to manufacture direction signals and similar devices.

THE PHILLIPS STEEL & WIRE COMPANY of Montreal, Que., has been incorporated with a capital stock of \$100,000 to manufacture wire, machinery, tools, etc. The incorporators are: Maurice Alexandre, Aubrey H. Elder, Felix W. Hackett and others.

THE LANE MANUFACTURING COMPANY of East Orange, N. J., has been incorporated by Edward Moley of Newark and William I. Lane of South Orange, N. J. The company is capitalized at \$10,000 and proposes to manufacture hydro-carbon burners.

THE CYNTHIANA (KY.) PLUMBING & ELECTRICAL COMPANY has been organized to carry on a general electrical wiring, plumbing and gas-fitting business, also to deal in electrical supplies and appliances, etc. J. F. Nooe is interested in the company.

THE J. S. MURPHY COMPANY of New York, N. Y., has been incorporated by E. V. McGovern, E. J. Healy and J. S. Murphy. 353 East Seventy-eighth Street, New York City. The company is capitalized at \$10,000 and proposes to do a general electrical engineering business.

THE UNION GAS & ELECTRIC IRON COMPANY of New York, N. Y., has been chartered with a capital stock of \$5,000 to manufacture electric and gas irons and other electrical devices. The incorporators are: S. Shack, M. Indender and S. Daniel. 1278 Webster Avenue, New York, N. Y.

THE PADUCAH (TEX.) ELECTRIC COMPANY has been incorporated with a capital stock of \$10,000 to construct and operate an electric plant in Paducah. The headquarters of the company will be located in Dallas. The incorporators are: J. F. Barnes, E. T. Paxton and E. M. Wise.

THE CUMBERLAND POWER COMPANY has filed articles of incorporation under the laws of the State of Delaware with a capital stock of \$100,000. The incorporators are: F. D. Buck, M. L. Horton and K. E. Longfield. The principal office of the company will be located in Wilmington, Del.

THE ELECTRIC ARC & WELDING COMPANY of Newark, N. J., has been chartered with a capital stock of \$50,000 to manufacture electric cutting and welding devices. The incorporators are: Carlos W. Curtiss of South Orange, Albion D. T. Libby of East Orange, and Walter J. Murray of Newark.

THE STANLEY ENGINEERING COMPANY of Wilmington, Del., has filed articles of incorporation under the laws of the State of Delaware. The company is capitalized at \$4,000,000 and proposes to install steam electric and hydraulic plants, etc. The incorporators are: N. C. L. Rimlinger, M. M. Clancey, F. A. Armstrong, local Wilmington (Del.) incorporators.

New England States

CONCORD, N. H.—Application has been made to the Public Service Commission by the Concord & Montreal Railroad Company, the Contoocook Electric Company and the Concord Electric Company. The Contoocook company wants permission to extend its transmission line through Concord from Contoocook, the railroad company asks for authority to sell energy to the Contoocook company from its plant in Franklin, the present to be delivered at Concord; the Concord Electric Company has asked the Commission for permission to draw up a joint lease with the Contoocook company, allowing the former in the future, if need should arise, to have joint use of the new lines being laid.

RUTLAND, VT.—A new contract has been signed by the Rutland Railway, Light & Power Company with the Staso Milling Company for supplying additional power for the amount of 717 hp.

Middle Atlantic States

ALBANY, N. Y.—Plans are being prepared by Frank N. Williams, state engineer, for a power plant to be built by the State Reservation Commission on Goat Island, Niagara Falls, to cost approximately \$100,000.

ALBION, N. Y.—Plans have been prepared for a new addition to the boiler plant at the Western House of Refuge for Women at Albion. William B. Dye is president of board of managers.

BROOKLYN, N. Y.—Plans are being prepared for the construction of a new power plant in connection with a large new capital building at Stuyvesant Avenue and Court Street by the Beth Moses Hospital. The cost of the entire works is estimated at \$100,000. Henry J. Nurick, 957 Broadway, Brooklyn, is engineer.

BUFFALO, N. Y.—Plans are under consideration by the Power Efficiency Corporation, 102 Clinton Street, for extensions and improvements to its plant. The company recently increased its capital stock from \$100,000 to \$350,000.

GROTON, N. Y.—Plans are under consideration by the Groton Electric Corporation for extensive additions and improvements to its system, including the construction of a large power plant at Freeville and the erection of a new transmission system, covering about 13 miles.

NEW YORK, N. Y.—The Lord Construction Company, 105 West Fortieth Street, New York City, has secured a contract for equipping 20 ocean ships with steam plant and engines.

UTICA, N. Y.—Notice has been filed with the Public Service Commission by the J. & E. Electric Company of an increase in capital stock from \$25,000 to \$50,000.

ATLANTIC CITY, N. J.—Negotiations, it is understood, are under way between the United States government and the Atlantic Electric Company, whereby the latter will furnish electricity to operate the plant of the Atlantic Loading Company at Elwood. The amount required, it is understood, is \$100 kw., which will be delivered to the plant at Elwood, a distance of 30 miles. The line will have a potential of 66,000 volts.

CAPE MAY, N. J.—Plans have been prepared by the United States government for the construction of a power house, 35 ft. by 10 ft., to be erected in connection with the proposed group of buildings.

HARRISON, N. J.—Plans have been filed and contract awarded by the General Electric Company for the construction of a new 6-story addition, 130 ft. by 245 ft., to its plant. E. M. Waldron, 665 Broad Street, Newark, has the contract.

MAYS LANDING, N. J.—Work has been begun on the erection of two large ammunition plants near Mays Landing, one by the Atlantic Loading Company, 71 Broadway, New York City, a subsidiary of the General Electric Company, to be located at Elwood, and the other the plant of the Bethlehem Loading Company, South Bethlehem, Pa., a subsidiary of the Bethlehem Steel Company. Employment will be given to about 800 persons. Arrangements are also being made for housing facilities for employees.

TRENTON, N. J.—The Crescent Insulated Wire & Cable Company, Olden and Taylor Streets, manufacturer of cables, electrical wire, etc., has recently purchased the property at 319-21 North Olden Avenue, which has a frontage of 110 ft. on North Olden Avenue and 275 ft. on Taylor Street. The company, it is reported, is contemplating extensions to its plant.

Construction

News of Projects, Plans, Bids and Contracts. Notes on Work Under Way

TRENTON, N. J.—Resolutions have been introduced to the City Commissioners in connection with plans now under consideration for establishing a municipal electric-light and power plant. The first provides that J. R. Fell, director of streets and public improvements, be authorized to negotiate with the Trenton Water Power Company to set a price on its plant, and the second for engaging E. E. Brownell, electrical engineer, for the purpose of estimating the cost of enlarging the local pumping station and other extensive improvements necessary to install a municipal lighting system in Trenton.

COLLEGEVILLE, PA.—The local power station of the Reading Transit & Light Company, which formerly furnished power for one end of the Norristown Street Railway division, has been dismantled and will be converted into a substation.

INDIAN CREEK, PA.—Contract has been awarded by the Mountain Water Supply Company for the construction of a new power house, 30 ft. by 70 ft., to the Rust Engineering Company, Pennsylvania Building, Philadelphia, to cost about \$35,000.

JOHNSTOWN, PA.—The plant of the Citizens' Electric & Gas Appliance Company was recently destroyed by fire, causing a loss of about \$75,000.

LEHIGHTON, PA.—The contract for the construction of power plant and 15 concrete buildings for the Atlas Powder Company at Reynolds has been awarded to Andrew Breslin of Lehigh.

PACKERTON, PA.—The Carbon Transit Company is considering plans for an extension of its system from Packerton to Jamestown, a distance of 1 mile.

PHILADELPHIA, PA.—Plans have been filed and contract awarded by the Quaker City Iron Works, Tioga and Richmond Streets, for the erection of a boiler plant at Edgemont and Tioga Streets.

PHILADELPHIA, PA.—The Fretz Company, Ontario and Brabant Streets, has awarded the contract for the construction of a new boiler and engine house at its plant to H. E. Brocklehurst, 512 West Norris Street, Philadelphia. The cost of the work is estimated at \$19,000.

PHILADELPHIA, PA.—The Lehigh Power Securities Corporation, which operates power plants at Harwood, Hanto and Allentown, developing a total of 73,000 kw., has announced that it is considering plans for the further centralizing of power plants in the Lehigh Valley. In connection with this project extensive additions to power plants are contemplated.

PITTSBURGH, PA.—Plans have been filed by the Arrott Estate, Arrott Building, for the construction of a new power building on Barker Place, to replace a similar structure, recently destroyed by fire. Contract has been awarded to Rose & Fisher, 821 Penn Avenue, Pittsburgh, to cost about \$15,000.

BALTIMORE, MD.—Cockran, Hill & Co., Wilkins Avenue and Brunswick Street, Union Stock Yards district, are contemplating the construction of a new cold storage and packing house, to cost about \$250,000.

FAIRMONT, W. VA.—Surveys are being made by the Monongahela Valley Traction Company for the erection of a high-tension transmission line from the Speedway to the new electric power plant at Rivesville. The new line will care for the needs of all residents of the Speedway section.

KINGWOOD, W. VA.—Extensive improvements are contemplated by the Inland Fuel Company of Greensburg at the plant of the Central West Coal Company at Kingwood, recently acquired, which will include the erection of a new power plant in connection with other buildings, at a cost of about \$75,000.

NEWELL, W. VA.—The plant of the Ohio China Company of East Palestine has been leased by the Novelty Clay Forming Company, manufacturer of electric porcelain specialties. The company is planning to remove its entire works to the new location.

OLCOTT, W. VA.—The Kanawha Central Power & Supply Company of Olcott, recently incorporated with a capital stock of \$100,000, proposes to construct and operate a power plant. The incorporators are S. B. Avis, Ivory C. Jordan, N. F. Young, John A. Thayer and F. A. Avis of Charleston.

North Central States

CINCINNATI, OHIO.—The Ohio Public Utilities Commission has granted the Cincinnati Gas & Electric Company permission to issue \$2,225,000 in short-term notes and the same amount in bonds to serve as security to the notes. The proceeds are to be used to complete the power plant on the river and to make other improvements in its distribution system.

CLEVELAND, OHIO.—Contracts have been placed by the Ohio Electric & Controller Company, 822 Citizens' Building, for the erection of a new plant, 60 ft. by 80 ft., at 5900 Maurice Avenue, S. E. The company proposes to make lifting magnets.

CLEVELAND, OHIO.—Permits have been granted by the city building department for the construction of an addition to the municipal electric-light plant. The building will be located at the north end of the present plant and will be 175 ft. by 169 ft., one story high. The cost of the building with equipment is estimated at \$800,000.

DAYTON, OHIO.—The Public Utilities Commission has authorized the Dayton Electric Light & Power Company to issue \$1,750,000 in bonds, for improvements to its plant and the purchase of new equipment, etc.

HOLGATE, OHIO.—A new company known as the Pleasant Light & Water Company has been organized to take over the municipal electric-light plant. The company is capitalized at \$10,000. William Peper is president and James C. Fast is secretary and treasurer of the company.

MILFORD, OHIO.—Plans, it is reported, are being prepared by the Miami Light, Heat & Power Company for the construction of a hydroelectric power plant, which will include 14 dams. A power house, it is understood, will also be erected in Loveland. For further information address L. J. Dolle, 705 Mercantile Library Building, Cincinnati, Ohio.

SPRINGFIELD, OHIO.—Preparations are being made by the Ohio Steel Foundry Company for building an addition to its plant, 30 ft. by 120 ft., one story, to be used for core room purposes. The erection of another building, 30 ft. by 100 ft., to be used principally for a repair shop, is under consideration. Contract has been awarded by the company for the installation of an electric furnace.

YOUNGSTOWN, OHIO.—The Miller-Smythe Electric Company is contemplating the construction of a new factory in Youngstown.

MCDOWELL, KY.—The Royal Elkhorn Coal Company, Ohio Building, Toledo, recently organized to develop a coal-mining project, proposes to install a drum for incline. R. J. Thomas, 211 Twenty-fourth Street, Ashland, Ky., is manager.

MANNINGTON, KY.—The Memphis Coal & Mining Company, a subsidiary of the Memphis (Tenn.) Gas & Electric Company, it is understood, will install an all-steel tippie at Mannington, at a cost of about \$40,000.

MAYSVILLE, KY.—The boiler, engine room and the entire equipment of the coal docks of the Chesapeake & Ohio Railroad Company at Maysville were recently destroyed by fire.

NORTONVILLE, KY.—Contract has been awarded by the Norton Coal Mining Company to the Ray Lumber Company of Madisonville for construction of an addition to its power house and supply house.

SOMERSET, KY.—The Southern Machinery Exchange of Somerset is reported to be in the market for the purchase of machinery as follows: One 150-kw., 250-volt direct-current generator and engine, or a direct-connected generating unit; a 225-hp. second-hand Diesel engine and four DeLancey lathes for spokes and handles.

ATTICA, IND.—The Indiana Public Service Commission has authorized the Attica Electric & Power Company to issue \$50,000 in stock and \$50,000 in bonds, the proceeds to be used for the construction of a new electric-light and power plant to take the place of the municipal electric plant recently destroyed by fire. As the bonded indebtedness of the city would not permit of borrowing more funds, it was necessary to form a private company to secure funds to rebuild the plant, which will generate electricity to be distributed by the municipal system.

EDWARDSPORT, IND.—The Indiana Public Service Commission has granted the Indiana Power & Water Company permission to issue \$210,000 in capital stock and \$725,000 in bonds, the proceeds to be used for extensions to its central power plant at Edwardsport. The company has contracts to supply power to a number of coal mines, and it proposes to build distributing sys-

terms in seven towns during 1918. The cost of the proposed improvements is estimated at \$881,924.

DECATUR, ILL.—The Illinois Public Utilities Commission has granted the Decatur Railway & Light Company permission to take over the plant and property of the Consolidated Light Company in Dawson and operate the same.

BRODHEAD, WIS.—Plans are being prepared by the Power Engineering Company of Minneapolis for rebuilding the municipal hydraulic power plant. The present plans provide for building an entire new power house, new flume and the installation of a waterwheel and generator, the latter to be of an umbrella type.

SUPERIOR, WIS.—The erection of a 13,000-volt transmission line is under consideration by the Great Northern Power Company to furnish energy to the Listman mill.

SUPERIOR, WIS.—Bids will be received by the Board of Supervisors of the County of Douglas, Superior, addressed to W. J. Leader, county clerk, Superior, until May 13 for the erection of a new court house in Superior, separate bids to be submitted as follows: (a) For general construction; (b) heating, ventilating and controlling; (c) plumbing and sewer work; (d) steel and iron jail work; (e) electric wiring and equipment. Plans and specifications may be obtained at the office of E. S. Radcliffe, United States National Bank Building, Superior, and J. W. Kroyer, Flatiron Building, Urbana, Ill., architects, upon deposit of \$25 for general contract and \$15 each for the others.

DES MOINES, IOWA.—The contract for electric wiring the new municipal court house has been awarded to the Whalen Electric Company, Polk Building. The cost of the building complete is estimated at about \$350,000.

LANSBORO, IOWA.—At an election held recently the proposal to issue \$7,000 in bonds for the installation of an electric-lighting system was carried.

NEOSHO, MO.—The Thurman-Davis Grain Company, it is reported, will rebuild its grain elevator, recently destroyed by fire.

OTTERVILLE, MO.—The installation of an electric-lighting plant in Otterville is under consideration. Jesse Starten is reported interested in the project.

BERN, KAN.—Bonds to the amount of \$9,000 have been voted for the erection of an electric transmission line from Seneca.

LURAY, KAN.—The city of Luray has awarded contract for a 75-hp. oil engine, a 50-kva. generator and a triplex pump to Fairbanks-Morse & Co. of Kansas City at \$14,000. The contract for construction of power house has been awarded to Florea & Laird of Luray at \$2,023.

PALCO, KAN.—Bids will be received by the city clerk, Palco, until April 16 for the construction of an electric-lighting system, separate bids to be submitted as follows: (1) for material and labor for erection of distributing lines in Palco and an electric transmission line from Palco to Plainville; (2) all labor for installing above; (3) material and labor for construction of a brick substation. Plans and specifications may be seen at the office of the city clerk, Palco, and at the office of George P. Taylor, engineer, Stockton, Kan.

PITTSBURG, KAN.—Bids will be received by the board of administration, Carney Hall, Pittsburg, care of J. A. Gamble, business manager, until April 16, for electric wiring, plumbing and steam heating for the Normal School addition, now under construction.

PLAINVILLE, KAN.—Plans have been prepared by the United Telephone Company for the erection of a new telephone building to cost about \$15,000. H. B. Winter of Manhattan is architect.

ST. FRANCIS, KAN.—The business men of Bird City are negotiating with the City Council to furnish electricity in that city. If the project is carried through it will mean extensions to the municipal electric plant, the erection of a three-phase transmission line, 16 miles long, and a distributing system in Bird City. Nothing definite has been decided upon and probably nothing will be done until after the war. T. W. Roelfe is superintendent of the municipal plant.

Southern States

PINE LEVEL, N. C.—The Citizens' Power & Light Company is considering the erection of an electric transmission line, 13 miles long, connecting two towns of 2500 and 5000 population, and building a substation in each town.

CHARLESTON, S. C.—The Charleston Consolidated Railway & Lighting Company is contemplating the installation of a turbine at its power house and also other improvements.

SUMTER, S. C.—The City Council is considering engaging an engineer to make investigations and prepare estimates of cost of the installation of an electric-light plant in Sumter.

DALLAS, GA.—The Dallas Utility Company, recently organized, is planning to install an electric plant on Pumpkin Vine Creek, Paulding County, to cost about \$10,000. The proposed project includes a development of about 250 hp., the erection of 5 miles of transmission line, etc. J. S. Boggs is manager.

METTER, GA.—The City Council is considering extensions to the municipal electric-light plant, at a cost of \$3,500.

BOWLING GREEN, FLA.—The Wauchula Light & Power Company is considering installing a small electric generating plant in Bowling Green for temporary use, pending the erection of an electric transmission line connecting with the Wauchula power plant.

TAMPA, FLA.—The Tampa Electric Company has been granted permission to extend its street car line on Twenty-second Street and also on Chapin Street.

ENSLEY, ALA.—The Tennessee Coal, Iron & Railroad Company of Birmingham is contemplating the installation of a 7500-kw. turbo-generator in No. 1 power station of the Ensley blast furnaces.

SELMA, ALA.—The Selma street railway system has been purchased by S. G. Adams for \$50,000. A new company has been organized under the name of the Selma Traction Company to operate the system. Improvements, including new extensions, it is understood, will be made by the new owners. J. D. Woodward of Warren, Pa., is president of the new company.

ARKANSAS CITY, ARK.—The contract for heating, plumbing and electric wiring of the new city hall has been awarded to Ellis Billings, at \$6,670.

EUREKA SPRINGS, ARK.—The installation of oil-burning engines and pumping equipment in the municipal waterworks station is under consideration by the City Commissioners.

RECTOR, ARK.—Bids, it is understood, will be received by the King Mercantile Company for a cotton gin and power plant, to replace those recently destroyed by fire. The loss on machinery is placed at \$25,000. Luther King is owner.

POTEAU, OKLA.—A movement has been started to install a new electric plant in Poteau. The promoters, it is understood, will soon ask for a franchise.

BEAUMONT, TEX.—Taylor & Dunshire of Beaumont, it is understood, are planning to construct an irrigation system and install a pumping station to irrigate about 2000 acres.

BEAUMONT, TEX.—The installation of a large pumping plant for irrigation purposes near Beaumont is reported to be under consideration by Broussard & Herbert of Beaumont.

BEEVILLE, TEX.—Work has been resumed on the construction of the municipal electric-light plant. The delay has been caused by injunctions, the first one preventing the city from building the combined water and light plant. It is expected to complete the lighting plant this year and the waterworks later.

BUFFALO, TEX.—The Dixie Girl Mining Company, Wheat Building, Fort Worth, Tex., contemplates the installation of a 10-kw. electric-lighting plant in connection with a zinc and lead mining development.

TEXAS CITY, TEX.—The Texas City Electric Light & Water Company is planning to build an electric power station and install a 100-kw. turbo-generator with a converter for street railway service and an emergency lighting unit. The company heretofore has purchased energy to operate its system.

Pacific and Mountain States

CHEHALIS, WASH.—The Commissioners of Lewis County have granted the Central Light & Power Company a franchise to erect electric transmission lines on the county roads west of Meskill, Chehalis and Wallville districts. The company expects to secure energy from the North Coast Power Company and supply electrical service in small towns west of Chehalis.

NORTHPORT, WASH.—The Electric Point Mining Company is planning to install an aerial tramway, to cost about \$50,000

It will have a capacity of about 20 tons per hour.

SEATTLE, WASH.—Preparations are being made by the Puget Sound Traction Light & Power Company to begin work immediately on an addition to its George town power plant. The cost is estimated at \$30,000.

GARDINER, ORE.—The Umpqua Light & Power Company, which recently took over the plant of the Gardiner Light & Power Company, is planning to install a new 125-hp. steam engine in place of the 40-hp. gasoline engine now in use. The company also proposes to extend its electric transmission line across the Umpqua River to Reedsport.

LONG BEACH, CAL.—Work has begun on the erection of a new substation at Eas Wilmington Junction for the Long Beach San Pedro and Los Angeles-San Pedro line of the Pacific Electric Company.

LOS ANGELES, CAL.—The board of education is contemplating the construction of an addition to the machine shop at the Manual Arts High School.

LOS ANGELES, CAL.—The finance and public safety committees of the City Council have been jointly instructed to arrange for the installation of an auxiliary lighting system in the receiving hospital and city jail.

LOS ANGELES, CAL.—According to a statement made by T. T. Woodman, Mayor of Los Angeles, an additional hydroelectric unit capable of developing 20,000 hp., utilizing water now going to waste, will be built in the near future by the municipal government of Los Angeles. Under the present charter of the city it cannot sell power at wholesale. The city is desirous of taking over the distributing systems of the Los Angeles Gas & Electric Company as well as other private electric distributing concerns.

ORANGE, CAL.—Steps have been taken by the City Council for the installation of electric street lamps on Chapman and Glassell Streets. The plans provide for ornamental standards mounted with a single lamp.

RIVERSIDE, CAL.—The Southern Sierras Power Company is contemplating the reconstruction of one of its main electric transmission lines extending from its hydroelectric plant located on Rush Creek in the Sierra Nevada range, a distance of 60 miles. The new line will increase the potential capacity of the Rush Creek plant by 5000 kw. The cost of the work is estimated at \$279,000.

SAN FRANCISCO, CAL.—Application has been filed with the Railroad Commission by the Sierra & San Francisco Power Company for authority to issue \$1,000,000 in bonds, the proceeds to be used for the construction of an additional hydroelectric plant on the middle fork of the Stanislaus River, the construction of storage reservoirs on the middle or the south fork of that river, building additional flumes, ditches, etc.

VERNAL, UTAH.—Application has been filed with the State Engineer by Charles B. Bartlett of Vernal for the use of 40 sec. ft. of water on Whiterocks Creek in Uintah County. The plans provide for a development of 950 hp. to be distributed in and near Lapoint. The power will be developed through three 6-ft. wheels under a 286-ft. head.

RONAN, MONT.—Negotiations are under way between the Council and the Mission Range Power Company of Polson for an extension of its electric transmission lines to Ronan, a distance of about 14 miles, to furnish electrical service here.

Canada

LONDON, ONT.—The Helena Costume Company, 190 King Street, is contemplating the purchase of a 60-kw., 110-volt, direct current generator, compound wound.

EAST BRIGHTON, QUE.—The Quebec Asbestos Company is contemplating a power development, to cost about \$30,000.

Miscellaneous

PANAMA.—Bids will be received by the general purchasing officer, the Panama Canal, Washington, D. C., until April 22, for furnishing manganese link pins, electric steel furnace, electric drill, copper magnet wire, split T connectors, storage batteries, rubber tires, etc. Blanks and information relating to this circular (1211) may be obtained at the above office or the offices of the assistant purchasing agents, 24 State Street, New York, N. Y.; 606 Common Street, New Orleans, La., and Fort Mason, San Francisco, Cal.

Notes on United States Patents

- 1,258,374. TELEPHONE-EXCHANGE SYSTEM; Franklin A. Stearn, Paterson, N. J. App. filed Oct. 28, 1916. Operator may listen from one cord to another at high rate of speed.
- 1,258,401. RAILWAY SIGNAL; Robert M. Gilson and Frank H. Nicholson, Pittsburgh, Pa. App. filed May 12, 1913. Improvements.
- 1,258,419. REMOTE CONTROL OF DYNAMO-ELECTRIC MACHINES; Alexander D. Kline, Schenectady, N. Y. App. filed June 12, 1914. Machines in the substations and as rotary converters.
- 1,258,423. VARIABLE ELECTRICAL APPARATUS; Fritz Lowenstein, Brooklyn, N. Y. App. filed June 28, 1910. Condensers.
- 1,258,473. PRIMARY BATTERY; Charles B. Shoemmel, Waterbury, Conn. App. filed Dec. 24, 1914. Effective contact between the positive elements and the current conducting and supporting means.
- 1,258,497. INDICATOR SYSTEM; William F. Straub, Chicago, Ill. Secondary device that responds to rapid changes of energization.
- 1,258,519. ARC LAMP FOR MOVING-PICTURE STUDIOS; William Bach and William A. Cunningham, New York, N. Y. App. filed May 16, 1916. Uniform distribution of light over a wide area.
- 1,258,529. PROCESS AND APPARATUS FOR PRODUCING ALKALI METALS; Johannes Brode, Ludwigshafen-on-the-Rhine, Germany. App. filed July 3, 1915. Improvements.
- 1,258,538. ELECTRIC SWITCH; William W. Dean, Chicago, Ill. App. filed July 18, 1913. Pressure-operated type.
- 1,258,540. SYNCHRONIZING SYSTEM; Amos P. Dixon, Newark, N. J. App. filed April 11, 1914. Maintaining motor-driven rotating mechanism in synchronism.
- 1,258,548. RADIOTELEPHONE; Carl R. Englund, East Orange, N. J. App. filed March 11, 1916. Improvements.
- 1,258,559. LAMP-SOCKET MEMBER; Monroe Fuett, Hartford, Conn. App. filed Sept. 26, 1916. Improvements.
- 1,258,577. PHASE-ADVANCER FOR DYNAMO-ELECTRIC MACHINES; Gisbert Kapp, Birmingham, England. App. filed Dec. 31, 1915. Energy to be obtained from a fly-wheel.
- 1,258,616. SIGNALING SYSTEM; Olin B. Frink, Elizabeth, N. J. App. filed March 25, 1915. Automatic and reliable system using a minimum number of wires between adjacent signals.
- 1,258,622. BLOCK-SIGNALING SYSTEM; Allen B. Kendall, Maywood, Ill. App. filed Aug. 7, 1913. System for controlling automatic signals on a single-track road.

(Issued March 12, 1918.)

- 1,258,641. ELECTRIC HEATER; John Berg and Lloyd W. Golder, Chicago, Ill. App. filed Dec. 4, 1916. Durable.
- 1,258,642. COMBINED ELECTRIC HEATER AND BOILER; Napoleon Bergeron, Montreal, Canada. App. filed June 8, 1917. Provides a heater whereby steam may be generated which will be supplied to a motor for actuating the generating apparatus.
- 1,258,646. ATTACHMENT PLUG; August Bouchery, Brooklyn, N. Y. App. filed Jan. 22, 1915. Improvements.
- 1,258,657. ELECTRIC TERMINAL; John Vuthbert, Chicago, Ill. App. filed Dec. 2, 1915. Wire clamping adapted for connecting circuit wires.
- 1,258,679. SWITCH - CONTROLLING MECHANISM; Edward W. Hedberg, Chicago, Ill. App. filed June 29, 1916. Improved limit switch.
- 1,258,686. CALLING DEVICE; William Kaisling, Chicago, Ill. App. filed Jan. 22, 1913. Automatic telephone systems.
- 1,258,721. ELECTRIC SWITCH; Lewis L. Tatum, Milwaukee, Wis. App. filed Nov. 6, 1911. Adapted for use in connection with solenoid.
- 1,258,722. SUSPENSION MEANS FOR HIGH-POTENTIAL WIRES; Chester H. Thordarson, Chicago, Ill. App. filed April 19, 1912. Minimizes the convection losses of energy.
- 1,258,758. MOTOR VEHICLE; Justus B. Entz, Cleveland, Ohio. App. filed Feb. 24, 1908. Improvements.
- 1,258,767. IMMERSION HEATER; William S. Hadaway, Jr., New Rochelle, N. Y. App. filed Jan. 28, 1918. Heater unit readily removable.
- 1,258,774. IGNITION SYSTEM FOR INTERNAL-COMBUSTION ENGINES; Ole Holen, Wyndmere, N. D. App. filed Dec. 26, 1916. Novel and improved circuit closer.

- 1,258,782. TELEPHONE-EXCHANGE SYSTEM; Charles W. Keckler, Newark, N. J. App. filed April 29, 1917. Improvements.
- 1,258,783. TELEPHONE-EXCHANGE SYSTEM; Charles W. Keckler, Newark, N. J. App. filed June 30, 1917. Improvements.
- 1,258,785. ENGINE-STARTING SYSTEM; Charles F. Kettering and William A. Chryst, Dayton, Ohio. App. filed Sept. 13, 1913. An electrical system which may be brought into operation, independently.
- 1,258,802. INSULATOR SUPPORT; Andrew J. Morgan, Framingham, Mass. App. filed May 22, 1917. Serviceable and convenient support for glass and porcelain insulators.
- 1,258,803. AUTOMOBILE-SERVICE RECORDER; John F. Ohmer and Frederick L. Ohmer, Dayton, Ohio. App. filed Oct. 6, 1916. Improvements.

1,259,385—Suspension Insulator

- 1,258,809. TRANSMITTING APPARATUS FOR ELECTRIC TELEGRAPHS AND THE LIKE; Louis M. Potts, Baltimore, Md. App. filed Oct. 18, 1912. When keyboard is operated at an irregular rate it permits a uniform rate of line transmission.
- 1,258,813. BELL; Louis E. Richmond, Cleveland, Ohio. App. filed Aug. 28, 1915. Electrical bell-sounding mechanism.
- 1,258,814. WIRELESS-BATTERY HOLDER; Earl H. Rollinson, Lyons Farms, N. J. App. filed May 29, 1917. Impossible for the cell connections to become disarranged.
- 1,258,816. INSULATOR PIN; Mortimer C. Rosenfeld, Cleveland, Ohio. App. filed Oct. 27, 1916. Permits the insulator to be turned in any direction.
- 1,258,838. METHOD AND MEANS TO CONTROL INDUCTION COILS; Paul R. Werner, Philadelphia, Pa. App. filed March 24, 1916. Adapted to be employed for the ignition of internal-combustion engines.
- 1,258,904. ELECTRICAL HEATING DEVICE; George A. Hughes, Chicago, Ill. App. filed Dec. 16, 1915. For warming the engine and radiator of automobile.
- 1,258,933. COMBINED BURGLAR AND FIRE ALARM; Edward C. Newson and Charles E. Beach, Jacksonville, Fla. App. filed March 18, 1916. Graphophone is automatically set into operation for announcing the audible signal to a telephone.
- 1,258,956. AUTOMATIC TELEPHONE SYSTEM; Arthur B. Smith, Evanston, Ill. App.

- filed March 25, 1914. Increases the capacity of an exchange without increasing the number of switches.
- 1,258,984. ELECTRODE FOR LUMINOUS-ARC ELECTRIC LAMPS AND PROCESS OF MAKING THE SAME; Frank Buchanan, Syracuse, N. Y. App. filed June 19, 1911. Combination of elements.
- 1,259,000. LIGHTNING PROTECTOR; West Dodd, Des Moines, Iowa. App. filed Oct. 23, 1917. For petroleum tanks.
- 1,259,040. MACHINE FOR MAKING MUSIC ROLLS; Edgar W. Myers, San José, Cal. App. filed Dec. 3, 1914. Improvements.
- 1,259,097. ALTERNATING-CURRENT DYNAMO-ELECTRIC MACHINE; William T. Hensley, Connersville, Ind. App. filed June 8, 1912. Sheet metal employed in place of castings.
- 1,259,160. APPARATUS FOR RECTIFYING HIGH-POTENTIAL ALTERNATING AND OSCILLATING CURRENTS AND ELECTROMOTIVE FORCES; William Walker, Pittsburgh, and Arthur F. Nesbit, Wilkesburg, Pa. App. filed June 3, 1913. Improvements.
- 1,259,170. ELECTRIC HAIR DRYER; Walter G. Trautman, Cleveland, Ohio. App. filed Dec. 20, 1911. Varies the heating by regulating the speed of the electric motor.
- 1,259,172. ELECTRIC REGULATOR; William A. Turbayne, Niagara Falls, N. Y. App. filed Feb. 11, 1915. Operates over a wide range of current or voltage values.
- 1,259,184. APPARATUS FOR COVERING THE PASSAGE OF CARS OR VEHICLES ALONG A RAILWAY AND THE CONTROL THEREOF; Thomas G. Willson, Swissvale, Pa. App. filed July 20, 1916. Improvements.
- 1,259,193. STORAGE BATTERY; John M. Ahlgren, Indianapolis, Ind. App. filed Oct. 6, 1917. Equal distribution of current to and from the plates.
- 1,259,202. ALTERNATING-CURRENT SOLENOID; Sydney N. Baruch, San Francisco, Cal. App. filed Aug. 31, 1916. Polyphase solenoid in which the tractive efforts of all of the phases are exerted in the line or axis.
- 1,259,206. CARBON-PILE SUPPORT; William L. Bliss, Niagara Falls, N. Y. App. filed June 5, 1916. Provides sufficient rigidity.
- 1,259,259. AUTOMATIC RAILROAD SWITCH; John Martin, Colton, Cal. App. filed Aug. 30, 1916. Electrically operated by a moving train.
- 1,259,268. ELECTRIC FUSE PLUG; Thomas E. Murray, New York, N. Y. App. filed Dec. 29, 1916. Improvement.
- 1,259,270. METHOD OF MAKING WELDED METAL RINGS; Thomas E. Murray, Jr., Brooklyn, N. Y. App. filed Oct. 4, 1917. Improvements.
- 1,259,271. ELECTRIC WELDING; Thomas E. Murray, Jr., Brooklyn, N. Y. App. filed Oct. 4, 1917. Objects are united in circumscribed area.
- 1,259,272. METHOD OF AND APPARATUS FOR ELECTRICAL WELDING; Thomas E. Murray, Jr., Brooklyn, N. Y. App. filed Nov. 9, 1918. Improvements.
- 1,259,273. METHOD OF ELECTRICAL BUTT-WELDING; Thomas E. Murray, Jr., Brooklyn, N. Y. App. filed Nov. 9, 1917. Improvements.
- 1,259,274. ELECTRIC WELDING MACHINE; Thomas E. Murray, Jr., Brooklyn, N. Y. App. filed Dec. 10, 1917. During its formation the weld will be caused to travel in a straight line.
- 1,259,275. PROCESS OF ELECTRICAL MOLDING; Thomas E. Murray, Jr., Brooklyn, N. Y. App. filed Dec. 10, 1917. Improvement.
- 1,259,295. STARTING SYNCHRONOUS MACHINES; Emanuel Rosenberg, Altrincham, England. App. filed Jan. 30, 1914. Starting and synchronizing device.
- 1,259,296. ELECTRIC SIGNAL APPARATUS FOR MARINE ORDER-TRANSMITTING MECHANISM; Walter S. Rush, New York, N. Y. App. filed March 15, 1912. Improvements.
- 1,259,310. AXLE COLLAR; Charles W. Starkner, Pittsburgh, Pa. App. filed Oct. 9, 1914. For positioning electric motors on the wheel axles of electric railway vehicles.
- 1,259,344. SUBMARINE CABLE; Edwin W. Beardsley, San Francisco, Cal. App. filed March 11, 1916. For the transmission of electric currents.
- 1,259,350. CROSSING SIGNAL; William A. Braden, Chicago, Ill. App. filed July 25, 1910. Signaling system for controlling traffic at street intersections.
- 1,259,368. DYNAMO-ELECTRIC MACHINE; James F. Curtis, Pitsaun, Pa. App. filed Sept. 10, 1914. Effective ventilation.
- 1,259,385. SUSPENSION INSULATOR; Charles Le G. Fortescue, Pittsburgh, Pa. App. filed May 25, 1914. For supporting high-potential lines.

This advertisement is not written with the idea of selling a dollar's worth of machinery or getting any unusual prominence in advertising, but because we feel that unless everyone is aroused at once to do his utmost to win the war this summer it will be too late, and we, who are staying at home, are not doing our full duty unless everyone will give and work cheerfully and abundantly—not only give and work OURSELVES, but see to it that our neighbors and acquaintances also give and work.

The N. E. L. A. 1918 War Convention

IN DECIDING to hold a war convention on June 13 and 14 the National Electric Light Association officials meet a real need for conference on the urgent problems of the times. The problems of normal years fall into the background, and the trials that now loom large call for the exercise of much patience, foresight, courage and ability. Central stations are not meeting merely to parade troubles. They are working constructively to overcome difficulties, but they ask co-operation and sympathy while they are doing it. An exchange of experiences will help the companies of enormous generating capacity, and it will be of still more value to the properties of medium and small size. Small properties feel most keenly the burden of present conditions, because in many cases they lack a margin of financial resource to withstand serious curtailment in net revenue due to abnormal swelling of operating expense. Therefore the lesson of the forthcoming Atlantic City convention may very wisely be directed to carry comfort to the operator of the property of moderate business volume. The convention will be effective in the degree in which it answers the two paramount questions of the day affecting central stations of average standing: First, how they can best help to win the war; second, how they can at the same time meet the pressing needs created by unparalleled demands for power, scarcity and high cost of capital, materials and labor, and inadequate rates.

Business Men Have Their Inning

REALIZING that without their efforts and resources the war cannot be won, American business men have given the country one of the most striking examples of what can be done in arousing industry to patriotic service and achievement. So prompt and so generous has been the response of business in this national crisis that the whole country has awakened to a profound faith in the big soul of business and has caught something of its spirit and felt something of its inspiration and determination. This week some three thousand of the nation's busiest manufacturers and merchants met in Chicago to deliberate over a constructive program for the war and the industrial struggle that is to follow it. It was not the gathering of any one industry but a great gathering of all kinds of business. While labor and agriculture have been organized for a long time in this country, it has remained for business in recent years to organize a democratic

form of expression. War-time organization of industry was the dominating subject, as well it might be, for has not the government within the past week showed its appreciation of some of the problems of business? The Webb-Pomerene bill, passed by Congress last week, assures the American business man a fighting chance in foreign markets, and the War Finance Corporation bill will provide him with funds to turn out the sinews of war for ourselves and our allies. Thus business men have a new hope for the future. With the government at their elbow to encourage and to help, and with the added incentive to greater accomplishment for the purpose of winning the war, nothing is impossible for business men. Moreover, the constant drive for greater and more efficient production will serve as an excellent training for world competition in foreign markets.

Economy in Power Plants

A VERY practical and effective paper on this subject was recently read by C. H. Parker of the Edison Electric Illuminating Company, Boston, and it is abstracted to the advantage of our readers in the current issue. It is probably altogether true that there are very few plants where no saving can be effected. Any carefully conducted boiler test can be assumed to yield better results than will be obtained in regular running, quite aside from all questions of steadiness of load. After all, economy in coal consumption comes back to care in stoking, whether in attention to the automatic machinery or in supervising the details of hand firing. Mr. Parker points out that it is a perfectly easy matter to cause a loss of 10 per cent in the heating value of the fuel by neglecting attention at this point, and he might have added that greater losses are too common.

In these days particularly, when unwonted grades of coal are being used, study of the details of combustion is all-important to economy. There are, too, minor losses, such as those due to water and excessive smoke. These are small on the whole, but the smoke matter is important on account of the indications it gives of improper firing, although a smokeless chimney does not necessarily mean an efficient furnace. Standby losses are in large measure dependent on the character of the load and the skill of the load dispatcher. Thorough watching of the performance of the boilers and furnaces gives the clew to moves for economy. In some plants overloading is a necessary evil, and here the judicious use of forced draft will often result in saving, especially through enabling the operator to work boiler and furnace at their most efficient output a larger proportion of the time.

Gas-Filled Lamps for the "Movies"

ONE of the very useful recent developments in incandescent lamps is the production of a special type for optical projection, especially in that wide field which is furnished by the "movies." Until within a very short time the arc lamp was the only reliance for projection on a practical scale. It combined two advantages of supreme importance for the purpose, great light-giving power and the extremely high intrinsic brilliancy which makes it possible to reduce the source of light to very small dimensions. The former quality is of great importance in projecting pictures at high magnification; the latter makes it relatively easy to get good definition with an optical system of moderate dimensions. The ordinary incandescent lamp was long ago developed into a projection lamp with a flat spiral filament which gave fair results on a small scale but was by no means good enough for motion-picture work. With the coming of the metallic-filament lamp still further improvements were made, but the low intrinsic brilliancy always stood in the way of successful competition with the arc. The gas-filled lamp has very materially changed the situation, so that now it is practicable to use it for regular projection work, gaining thereby the immeasurable boon of steadiness, a quality in which the arc is unhappily lacking.

The intrinsic brilliancy of even the gas-filled lamp is only about one-fourth that of a direct-current arc, so that particular pains have to be taken in the design of the projection apparatus to make up for this loss by higher efficiency of utilization. The brilliancy of the filament is limited by its possibilities of life, and it is also dependent on the actual diameter of the filament. The larger this diameter, the higher the brilliancy that can be secured without loss of effective life. In the most recent form of lamp for projection purposes, as is well shown in our paper by R. P. Burrows and J. T. Caldwell, an arrangement of filament is adopted which brings all the coils into very nearly the same plane compressed into as small an area as practicable. This arrangement gives a distribution of light strongly outward from the front and rear of the plane and consequently in the directions most useful for the projection. The filament must be placed in a bulb of relatively small diameter in order to afford available space for placing the projecting system, and hence the filament is actually mounted in a long cylindrical bulb to obtain this advantage with the requisite bulb space. The optical system itself which furnishes the working beam consists of a spherical mirror of rather short-radius behind the filament and a Fresnel lens of short focus in front. The light which proceeds from the rear of the filament plane is reflected back upon it, and by careful focusing the system of images can be made to fall between the loops of the actual filament, so as to produce a virtually nearly uniform plane of light in the focus of the lens.

With this sort of source it is possible to use a projection lens of wider aperture than usual, since there is no longer danger of magnifying the flicker of the arc lamp. With an equipment of this kind it is easy to throw a picture 12 ft. by 14 ft. (3.7 m. by 4.3 m.) in dimensions on a first-class screen up to at least 90 ft. (27.4 m.) distance. In other words, one can do the

regular standard work of the motion-picture theater with highly satisfactory results and with a minimum of care and trouble. The standard type of lamp used is for 20 amp. and about 30 volts. It is superlatively easy to work this off an alternating-current circuit, and a special transformer has been developed for this purpose with provision for taking care of the variations in line voltage and for cutting out the rush of current into the cold lamp at the starting. On direct current a motor-generator or its equivalent has to be used unless one cares to waste an inordinate amount of energy in a rheostat. Oddly enough, this just reverses arc-lamp practice, where direct current is relatively easy to use and alternating current involves some trouble. The advantage of the incandescent lamp for projection lies in the fact that when once adjusted it stays on the job without further trouble, eliminating flicker, always staying in focus and saving energy. The problem of beating the arc at its own game has been no easy one, but it seems to have been finally solved in a very successful and practical manner.

Preparing for Industrial Load

IN THESE days of daylight saving the uninformed public imagines that central stations are likely to lose most of their revenue and save most of their coal. The said uninformed public may, however, acquire a new idea or two by noting our article in the current issue on what is being done in one New England city in the way of preparing for industrial load of rapidly growing dimensions. The scene of operations is New Bedford, where textile work is on the jump, and the present article supplements that in our Feb. 23 issue by giving additional details of the big station in that city. It gives some adequate impressions of the requirements of the present situation in dealing with increasing service. The piping arrangements of the new plant in particular are deserving of comment. The water supply has been the subject of particular study. The feed-water system is installed in duplicate, with duplicate connections for supplying the make-up water from the city mains, the general supply, of course, being taken from the condensate well. To save using city water a portion of the condensate is utilized for circulation around the bearings of the turbo-generators and then fed back again to the well. The supply to the boilers is measured by flow recorders, one for each of the 5000-hp. feed-water heaters, with an auxiliary meter to check their performance.

The steam piping has been similarly devised for flexibility of connections and short runs to the generators. The boilers deliver steam into a horizontal steam main next the well between the boiler and turbine rooms, and from this is fed a steam bus across the turbine room so that each generating set can be reached by a short connection. This sectionalizes the piping effectively and obviates the need for a multiplicity of steam leads into the turbine room. In connection with the turbo-generators it is worth noting that an air-spraying equipment with a capacity of 50,000 cu. ft. (1415.8 cu. m.) a minute is provided to condition the ventilating air for the generators. Another striking evidence of the magnitude of the work is found in the switchboard and feeder equipment. To this strictly electrical work

devoted a four-story bay of which the electrical arrangement was shown in our previous article. The interesting point about it is that it actually provides for more feeders and switches than the great hydroelectric plant at Keokuk, one of the biggest in the country. So much for the necessities of a great and intricate industrial load. To secure immunity from the danger of switchboard troubles the whole system has been isolated with particular care, every oil switch being housed in a compartment of its own, and the commercial lighting and street-lighting equipments are also thoroughly separated. Similarly the 2300-volt and 13,200-volt bus systems are completely separated from each other, and each is provided with duplicate buses parted from each other by fire walls. From the 2300-volt busbars are served the six 750-kw. transformers which feed the 22,000-volt system for the more distant part of the distribution. It is rare to see a more complete scheme for safety and continuity of service in a plant requiring from the nature of its load an unusually comprehensive order equipment.

The Increasing Use of Fuel Oil

THE great shortage of coal during the past winter impelled many plants to operate on fuel oil, until, our article in the issue of last week indicates, in New England alone oil-burning plants reach an aggregate of nearly 100,000 hp. Fuel oil has come into use also in heating plants for ordinary commercial buildings, for public buildings, and even for private residences. Of course, in other parts of the country the use of fuel oil has been familiar; that it has not been more widely used is due to a complication of reasons, chief among which is the fact that its price has varied in an entirely erratic fashion owing to various familiar natural and artificial causes. If its use in a particular case turned out to be economical, it was always a question as to how long it would stay so. The present state of affairs, however, puts an entirely new phase on the matter. Not only is coal at a very much higher price than usual, but transportation from the coal mines has been extremely difficult. Fuel oil, however, comes into New England ports in tankers, which in the main have not yet been commandeered, and is distributed in tank cars which cannot well be used for other purposes. The usual oil is chiefly so-called "topped" oil from the Southern or Mexican fields, oil from which the lighter distillates have been separated. It runs a little heavier than 18,000 B.t.u. per pound, about 150 gallons (37.8 l.) being equivalent to a ton of good steam coal. As regards the mere matter of price, when three years ago such oil could be obtained for about 2½ cents a gallon it was practically on an even footing with steam

coal at the same period, at about \$3.75 per ton. It now ordinarily costs about twice the figure just given and has run even higher, so that as regards fuel value it is safe to say that it is kept practically on a par with coal. There are, however, some very marked advantages in the use of oil as such, particularly in the matter of labor and general maintenance. If properly handled, it gives substantially smokeless combustion, although very sensitive to improper treatment in this respect. It also keeps the heating surfaces cleaner than coal and is very much easier to store and handle than solid fuel. The whole question of ash is also eliminated and the upkeep of the boiler room somewhat lightened. A very characteristic advantage is the ease and quickness with which boilers can be forced to the limit in their output and kept there for long periods if necessary, since there is no reduction due to necessary cleaning of the fires. The added output can be assumed very quickly, and if boilers have to be kept in reserve they can be kept hot by oil fuel at a minimum cost. This advantage is particularly striking in cases where the plant is completely shut down for the night and has to start up at full capacity in the morning, as in textile working.

With proper equipment there seems to be usually a gain in boiler efficiency from the cleaner and steadier fires furnished by the oil, as well as greater steadiness in the steam pressure owing to the uniformity of conditions. Last week we gave details of the results in typical plants, all of which show material improvement in the performance of the boiler plant and great advantages of convenience as well. In the long run the question is that of the relative cost and availability of the two fuels. With a thoroughly modern boiler plant burning coal the boiler efficiency can be kept at a point where the advantage of oil fuel is not conspicuous. We are rather inclined to the opinion that the most marked gains have resulted in substituting a thoroughly first-class oil-firing system for a rather indifferent coal-firing system. There are many instances, however, of this very kind, and they are furnishing perhaps the most advantageous opportunities for changing to the use of oil. Its employment in relatively small plants, as in heating apparatus, offers advantages of convenience not lightly to be put aside. They are perhaps more striking here than in big plants, and the use of oil even in domestic furnaces has very conspicuous advantages in cleanliness and ease of fuel supply. At present prices of anthracite oil look attractive, and if the oil supply from the Southern and Mexican wells can be well kept up it would seem probable that a large increase in oil firing is likely to take place. The chief difficulty is that the use of fuel oil on ships has grown enormously. The needs of the navy are enlarging very rapidly, and the price of oil is likely to soar.

LONG-SPAN construction, characteristics of commonly employed dielectrics, selection and arrangement of motors for woodworking and features of a steam plant built to supplement a large Canadian water-power development will be the basis of several articles to be presented in the ELECTRICAL WORLD shortly. The article on long-span construction will dwell on the problems that differ

The Coming Issues

from those usually encountered in line construction and will contain the opinions of many prominent Pacific Coast engineers. The article on characteristics of dielectrics should interest designer and operator alike, as only through knowledge of their properties can dielectrics be properly applied to electrical apparatus. Central-station conditions will be reviewed in another article.

Central Stations Meeting War Demands

Great Volume of Business Pressed Upon the Companies—Labor Short and Materials High and Scarce—Many Men in the National Service—
Power Famine at Niagara

ANNUAL reports made by the electric utilities to their stockholders carry this year strong reminders of the war, of the extraordinary economic conditions of the times affecting costs of operation and of the tremendous power business urgently pressed upon the companies. The great bulk of the properties are operating with forces depleted by men in the national service, and they are in effect turning their physical plants to such ends as the government authorities desire.

NIAGARA FALLS POWER COMPANY

Significant of the shortage of power in a district where war industries are operating at high pressure is the statement of Stacy C. Richmond, president Niagara Falls Power Company: "It is confidently believed that double the present output of all the existing plants would soon be absorbed for at least the duration of the war."

"Throughout the year the demands on both companies for power were far in excess of the plants," says Mr. Richmond. "Practically a power famine now exists at Niagara."

The Niagara Falls Power Company, like all other properties, felt the influence of large sales and of heavy costs.

"Increases in production and sales by your companies," says the president, "resulted in substantial increases in gross revenues. The increases were more than offset by greater operating costs and by large increases in taxes."

As a further precautionary step it also was considered proper by this company to appropriate from surplus a substantial reserve against certain contingent liabilities, consisting in the main of possible further requirements under constructions which may be placed on recent war and excess profits tax laws.

The Niagara company calls attention to the expense of protecting both American and Canadian plants against lawlessness as one of the recent increases in operating cost. Military and private guards are stationed at the Canadian plant and private armed guards at the American plant. A protective inclosure has been built around the American plant.

UNION GAS & ELECTRIC COMPANY

The Columbia Gas & Electric Company, Charleston, W. Va., controls, among other properties, the Union Gas & Electric Company, Cincinnati.

Among the property developments of the year, A. B. Leach, the president, mentions the fact that in order to guarantee an adequate coal supply the company acquired a one-half interest in the Wood Coal Company, Logan, W. Va. "The mine owned by this company," he says, "has a seam of the highest quality steam coal and is sufficient to meet the coal requirements of your company's subsidiary properties for many years."

As indicating the favorable prospects for the electric business of the Union Gas & Electric Company, it stated that a third 30,000-kw. turbo-generator has been ordered for delivery in 1919 for the new power plant making a total capacity of 90,000 kw. Notwithstanding numerous delays due to congestion in manufacturing and railroad deliveries, the new plant is nearing completion.

DETROIT EDISON COMPANY

Alex Dow, president Detroit Edison Company, serves in the report of that company that during latter months of 1917 there was a persistent change in the products of the principal industries served from those of peace to those of war.

"The earlier manufacture of munitions for export was comparatively small in this territory," says Mr. Dow. "It is now an important part of local industry and is apparently to become more important. The change has been made thus far, and continues to be made, with no apparent effect on our sales of energy. Up to the end of the year 1917 there had been no notable addition because of munitions manufacture to the demands upon us, the work in progress being done by diversion of existing power supply to the new uses. Our increase during 1917 has been due to normal growth."

In speaking of the increase in operating ratio from 54.5 per cent in 1916 to 63.8 per cent in 1917, Mr. Dow says that this is due to increased coal cost. "We are paying higher wage rates, and everything going into operating expense has increased seriously in cost. But by careful management and with the loyal help of our employees we have been able to keep all expenses excepting fuel, down to a reasonable proportion of total earnings. Coal, however, has cost out of all reason and has been scarce and of poor quality, notwithstanding its high price."

Mr. Dow pays a fine tribute to the men who have responded to the call to arms. Many of the young employees have gone. The total number who have joined the colors to Dec. 31, 1917, was 311.

Now senior skilled men, whom it is difficult or impossible to replace, are being taken by the government for special service.

"Thus far," Mr. Dow adds, "we have not asked for exemption of any employee, and we wish to avoid doing so. Neither have we filled all the vacancies. We have asked our operating employees to close their ranks so far as practicable, behind the men who went off and they have loyally done so."

An example of what it has been possible to do is cited by Mr. Dow: "We have been able, without losing the good will of our customers, or without impairing service, to do away with some of our routine bills, for instance, since midsummer we have been rendering bills to our Detroit residence customers for two-month periods, instead of for one-month periods, as formerly."

out the necessary work is being done with a less number of employees, both relatively and actual."

One effect is that the company is paying higher average wages in every operating department, partly in recognition of increased cost of living and partly in recognition of increased efficiency.

Mr. Dow notes, in speaking of construction expenditures, that the net increase of plant investment during the year was \$8,069,496. This, though the largest amount expended by the company in any one year, is less than it was planned to spend. Much new work has been deferred indefinitely. Construction was accomplished under difficulties, labor costs were high, materials costly and scarce, machinery under contract for delivery has been delayed to give right of way through shops for United States requirements, and even weather conditions have been adverse to quick and cheap construction.

Among the larger items of construction deferred indefinitely, Mr. Dow mentions, is a proposed new power plant on the St. Clair River south of Port Huron. Steam turbines and boilers purchased for this plant will be put in storage for the present.

The policy as to line extensions is: "We have latterly refused to make any considerable extension of lines, excepting for supply of power to factories undertaking government contracts. Our intention is to carry out our engagements made before the war and to connect business on existing lines up to the capacity of these lines and of our power plants; but, excepting for extensions for national service, as stated above, and excepting the few cases where a refusal will work very great hardship, to decline to make line extensions."

Reverting to the change in character of industry from peaceful uses to war orders and stating that additions to existing factories and numerous new factories being erected are, with few exceptions, to be devoted to war-material production, Mr. Dow adds: "It is our expectation, therefore, that our sales of industrial power, which are the most important part of our business, will be fairly maintained."

Gross revenue of the company increased 21.9 per cent in 1917 over 1916, and output 22.9 per cent.

MONTANA POWER COMPANY

John D. Ryan, president Montana Power Company, notes that in spite of disturbed labor conditions, interfering with mining and smelting operations, and affecting practically all large industries, there were substantial increases in lighting and power consumption in small towns and in other branches of the business. Gross earnings increased nearly 11 per cent over 1916.

About \$3,600,000 was expended during the year for new construction. Some construction work suspended temporarily last October, owing largely to labor conditions, will be resumed and carried to completion in 1918.

Forecasting the new year, Mr. Ryan says: "The outlook for business in general in Montana during the year 1918 is very good. All of the principal products of the State will doubtless bring higher prices, and as a result we may expect the usual increases in the lighting and small power business of our branches and towns, as well as increased income from electrical operations of railroads and the larger power business,

which we estimate will more than offset the probable increases in higher cost of labor and materials and any increase in taxes."

EFFECT OF WAR ON NEW YORK COMPANIES

The annual report of the Consolidated Gas Company, New York, for 1917 refers generally to conditions affecting its electric subsidiaries, which include the New York Edison Company and United Electric Light & Power Company, in part as follows:

The effect of the war upon the cost of producing and distributing gas and electrical energy has already been very disastrous and will be much greater during the present year than it was in 1917.

The price of practically all the materials and supplies required in the production and distribution of gas and electricity increased very substantially in 1917. The same was true of labor. The price of boiler coal used in generating electricity increased 59.2 per cent, and that of anthracite and bituminous coal used in gas manufacture 11.3 per cent, the average increase in the price of all varieties of coal used amounting to 34.3 per cent.

Coupled with the increase in the cost of coal has been the difficulty of obtaining it as well as a marked inferiority in its quality, causing an excessive consumption as well as impairing the capacity of the various plants.

As an insurance against any possible contingency which might interrupt the normal supply of coal, the lighting companies for years past have made it a practice to carry a large stock of coal on hand. This stock has generally been accumulated during the summer months, when shipping conditions were favorable. Mining and railroad conditions during the summer of 1917 were such, however, that the stocks of coal could not be brought up to the full quantities required and always theretofore maintained.

The increase in the cost of labor has also been very considerable, the principal causes for this being an extraordinary demand for men on the part of contractors engaged in the manufacture of war munitions and supplies, the building of cantonments and unusual activities in local shipbuilding yards, including the navy yards. The available supply was greatly diminished by the effect of the enlistment of a great many men in the army and navy and the conscription of many others.

Notwithstanding some improvement in the revenue from the sale of residual products, credited to the cost of gas manufacture, the increase in the combined operating expenses of the gas and electric companies amounted to \$9,336,003, including the increase in taxes (\$1,486,626) and the increase in operating expenses due to the greater quantity of gas and electricity sold (\$2,413,332).

More than 1050 employees of the Consolidated Gas Company and its affiliated gas and electric companies are now serving in the army and navy, representing every grade of employment from departmental superintendents to day laborers.

The technical and engineering departments were particularly affected in this respect, the demand for the services of men thus qualified and the inducements offered them to join the various branches of the service having resulted in a great many enlistments. In the various clerical departments the difficulty of obtaining men to fill the vacancies thus caused resulted in the employment of many women, who are performing their duties in an entirely satisfactory manner.

When the first Liberty loan 3½ per cent bonds were issued employees of the Consolidated Gas Company and affiliated gas and electric companies were offered the privilege of paying therefor in installments. This privilege was availed of by 12,357 employees, who subscribed for an aggregate of \$847,700. Similar action was taken in respect of the second Liberty loan 4 per cent bonds and 7478 employees subscribed for an aggregate of \$511,750.

Sales of electric energy during the year, including sales to the Third Avenue Railroad, the Brooklyn Rapid Transit Company and the New York, New Haven & Hartford Railroad, amounted to 749,827,761 kw.-hr., an increase over the previous year of 11.37 per cent.

METHOD OF IMPROVING POWER PLANT ECONOMY

Reiteration of Principles Involved in Efficient Combustion of Coal, with Suggestions as to How This End Can Be Attained

ECONOMY in the use of fuel in power plants was discussed recently before the sanitary section of the Boston Society of Civil Engineers by C. H. Parker, superintendent of the generating department, Boston Edison company. He emphasized the importance of even a 1 per cent saving in the 32,000,000 tons of bituminous coal which the Fuel Administration estimates New England uses yearly, pointing out that this would release one 10,000-ton collier for a year and that the railroads could release 6400 50-ton coal cars one trip a year for other work as a result.

The first part of Mr. Parker's remarks referred to principles of efficient combustion. This was followed by a number of practical suggestions bearing on plant economy. He pointed out that there are many plants where substantial savings can be made and very few plants where no saving at all can be effected. The loss due to combustibles in the ash, the speaker pointed out, depends on the type of grate or stoker and the care taken by the firemen in firing and cleaning the fires. This loss may amount to 10 per cent of the heating value of the fuel. The openings in the grate or stoker should be proportioned to the kind of coal to be used, a non-coking coal requiring smaller openings than a coking coal. It is often possible to save a lot of the siftings, especially with stokers, by installing proper hoppers or pans to catch them and keep them free from the ashes. A periodical examination of the ashes carted away was suggested.

The loss due to water in the coal is twofold. First, if coal containing moisture is purchased it is very expensive, as each per cent of water means that a certain percentage of coal paid for cannot be utilized thermally. Second, the moisture has to be evaporated and superheated to flue temperature. Together these considerations mean about 1.1 per cent loss for each 1 per cent water in the coal. Sometimes it is helpful to wet the coal just before firing on ordinary hand-fired grates to prevent the rapid release of the volatile hydrocarbons and give them a chance to be consumed also. On some overfeed stokers wetting may prevent excessive sifting. In each of these cases the loss due to evaporation and superheating to flue temperature is present, but the other gains more than offset it. The water acts only in a mechanical way and adds no heat.

The loss due to visible smoke is usually very small, rarely reaching 1 per cent of the coal fired, but dense smoke quite often means bad conditions elsewhere. If the coal is fed in excessive quantities, considerable hydrocarbon may be liberated without being burned. Smoke may also indicate too small a combustion chamber. A smoky chimney, however, may be more economical than a clear chimney if the latter is obtained by excessive air dilution.

Standby losses may be considerable in plants having a fluctuating load. They consist of (1) coal required to start up cold boilers, (2) coal used to bank fires during shut-down periods, (3) heat lost in shutting down boilers, and (4) heat lost in water blown off to get rid of mud and scale from mud drum. The magnitude

of these losses is dependent on the character of the load that is carried. Where boilers are not needed for more than twenty-four hours it is usually cheaper to let them go out and build new fires rather than bank them.

Flat grates are fired by hand satisfactorily up to 150 hp. rating on return-tubular boilers and up to 300 hp. on water-tube boilers. Above these sizes smokeless combustion is difficult without special arrangements, such as Dutch ovens, the Chicago settings or steam jets.

Steam jets pointed downward to force extra air over the fire at the front wall, through the side walls, or even through the bridge wall, and mix it with the volatile matter from the coal often produce good results by improving the efficiency and reducing the amount of smoke. Unfortunately, when the operation of the jets is left to the fireman results as good as those from tests are not always obtained. The jets should be used only while the volatile matter is being liberated and should be shut off afterward until the next charge of coal is fired. Steam air injectors can be made automatic and therefore independent of the fireman, but they need adjustment to obtain the best economy.

THE DIFFERENCE IN COALS

Semi-bituminous coals, such as New River, Pocahontas, Clearfield, etc., work well with a fire 12 in. to 14 in. (30.5 cm. to 35.5 cm.) thick, and should be fired every ten or fifteen minutes. The more volatile coals used in New England are harder to burn efficiently and the fires should be thinner. With our most volatile coals the fire should not be more than 7 in. or 8 in. (17.75 cm. to 20.3 cm.) thick. The thinner the fire the more often should coal be put on.

Interest on the investment, depreciation, repairs and power for operation cost more with mechanical stokers than with hand firing, but mechanical stokers make possible the use of poorer fuels with efficiency as high or higher than is obtainable in hand firing with better grades of fuel. All underfeed stokers can burn the cheaper grades of coal economically, and one man can fire 3000 hp. or 4000 hp. of the inclined type, but not so many of the horizontal type, where hand cleaning is necessary. At the present time, however, unless an addition to plant is required by reason of increased load, the question of fuel saving resolves itself into the best use of the existing plant rather than replacing it with new, as the costs are very high and deliveries cannot be made for a year or more in many cases.

A control panel centrally located, with all of the meters and controls for the operation of one or several boilers mounted on it, is worth its cost, as the stoker operator can tell at a glance what fires need attention and what ones are operating satisfactorily. Without this a man must move continually from one fire to another for inspection of the conditions that exist.

A log sheet showing the starting and stopping of machines and boilers, pressures, temperatures, vacuums and loads carried is wasted effort and material unless it is studied and the facts discovered are acted upon for increasing the efficiency.

Where coal is very expensive or there is not exhaust steam enough to heat the feed water economizers are of advantage. When high boiler pressures are used, resulting in high flue-gas temperatures, they result in considerable saving. In existing plants where boilers are poorly designed and have to work at heavy over-

loads, it might be cheaper to increase the capacity by installing economizers than by adding more boilers.

Some plants are called upon to carry considerable overloads for a short time, either periodically or occasionally. Forced draft will often save fuel and money in such cases. If these periods are frequent it may be advisable to install the more expensive fan equipment, as that will only use 2 per cent to 4 per cent of the steam; but if these occasions are few, it is cheaper to install a steam air injector that may use from 5 per cent to 10 per cent of the steam or more. The standby losses of boilers, such as banking, are considerable, and if boilers have to be kept banked for

long periods to cover a few emergencies, auxiliary forced draft will be found advantageous.

The steam loop is a simple means of returning the condensation in piping to the boiler and is adequate for small stations. In plants of several units, however, it does not work so well and the drip return system may be used. By these means all high-pressure drips are saved and the bleeder steam from the nozzle in the upper tank can be put into the feed-water heater and the heat saved. The exact saving depends on the men operating the plant and what wastage of steam would be allowed from drips if the automatic arrangement were not used.

Assuring Satisfactory Fuse Operation

Proper Installation and Renewal of Transformer Fuses Are Essential to Good Service and the Protection of Apparatus—Necessity of Standardization of Fuse Types

THE transformer fuse is usually looked upon as a necessary evil; it is purposely made the weak link in a system in order to protect by its weakness other more important apparatus. But this weakness must be dependable and predetermined. A fuse failure means either premature failure or incomplete failure; the first results in poor service and the latter in destruction of apparatus.

No transformer fuses would be used if other more dependable apparatus could be installed at a permissible price. However, so long as conditions and available apparatus remain as at present, distribution transformers of moderate size must be fused; hence means have to be devised for obtaining the best possible results from an admittedly recalcitrant device.

Among things essential to the satisfactory action of transformer fuses are proper installation, in the first place, and proper renewal of fuse elements at all times. Transformer fuses are often blamed for shutdowns and apparatus burn-outs which are really the results of incorrect renewals rather than of inherent fuse troubles. Many of these troubles will be eliminated if employees are carefully supervised in handling fuse renewals and furnished at all times with proper materials.

The equipment of every troubleman engaged in this class of work should include a suitable container for fuses. If this is standardized and extra sets, completely filled, are kept in stock at headquarters, emergency demands will be more easily met. A fuse kit used by one company in the far West is shown in an accompanying illustration. This company operates 2300-volt and 11,000-volt distribution circuits. The 2300-volt link fuses for the ordinary transformer insulator-type cut-outs, together with larger sizes for expulsion-type installations, are placed in the lower partitioned section of the case, while the 11-kv. fuses are contained in waterproof cylinders carried in an upper tray. A pair of rubber gloves, extra expulsion fuse holders and a treated wood puller complete the outfit. A fuse puller of the pincer type is to be preferred to those with spring metal jaws, first because of the ab-

sence of metal and secondly because the wood type may be used for pulling fuse holders of a variety of sizes and affords a positive grip on any.

To avoid mistakes in selecting fuses, a stamped aluminum plate is soldered to one end of each fuse compartment, showing the size fuse contained therein. A number tag is fastened to each 11-kv. cylinder for a similar purpose. To the inside of the fuse-kit cover is attached a printed schedule of the fuse sizes required with the various types of transformer stations used on the sys-

FIG. 1—CABINET THAT AVOIDS WRONG SELECTION OF FUSES

The box is constructed of No. 24 gage galvanized sheet iron. The upper tray and the partitions in the bottom are of No. 26 gage, while the tubes are No. 30 gage. The upper edge of the case is reinforced with $\frac{1}{4}$ -in. (6.4-mm.) round iron, and the edge of the cover is similarly reinforced with $\frac{3}{16}$ -in. (4.8-mm.) stock. The box measures 18 in. by 9 in. by $5\frac{1}{2}$ in. (15.7 cm. by 22.9 cm. by 13.9 cm.). The bottom partitions are $1\frac{3}{4}$ in. (4.4 cm.) deep. The tray is $17\frac{1}{2}$ in. by $8\frac{1}{2}$ in. by $2\frac{1}{4}$ in. (44.4 cm. by 21.6 cm. by 5.7 cm.) and rests directly on the lower partitions. The cylindrical containers for 11-kv. fuses are 14 in. (35.6 cm.) long and $1\frac{1}{4}$ in. (3.2 cm.) in diameter.

tem. This information is considered especially important since troublemen stopping to figure the proper size may make serious errors.

The company employing this box ordinarily fuses 2300-volt transformers for double load and 11-kv. transformers for from 50 to 60 per cent overload. The intention is to protect 2300-volt transformers primarily

against short circuits, while 11-kv. transformers are given what is as nearly an overload protection as is possible with the use of fuses and consistent with good service. Obviously the higher the overload for which transformers are fused the better the guarantee against interruption to service, but on the other hand the transformer protection is reduced. Consequently the lower-

SIZES OF FUSES FOR 1-TO-100-KW. TRANSFORMERS RECOMMENDED IN FUSE-KIT LIST—FUSE RATING IN AMPERES

Size of Each Transformer (Kw.)	2300-VOLT			11,000-VOLT			
	Single-Phase	Open-Delta*	Closed-Delta	Single-Phase	Open-Delta*	Closed-Delta	Three-Phase Transformer
1	1	4	1	2	2	2	2
3	3	3	3	2	2	2	2
5	5	5	5	2	2	2	2
7½	10	10	10	2	2	2	2
10	10	10	15	2	2	2	2
15	15	15	20	2	3	3	2
20	15	20	25	3	3	5	2
25	20	25	30	3	5	5	2
30	25	30	40	5	5	8	2
50	40	60	75	8	10	12	5

100	75	100	100	15	15	20	8

*Middle lead. Outside lead is same as single-phase.

priced lines of transformers are fused for larger percentages of overloads than the higher-priced.

It is evident from the accompanying table that 11-kv. transformers of less than 15 kw. are protected against short circuit only and not against overload, the reason being that 11-kv. fuses smaller than 2 amp. are very unreliable and not recommended for practical service. The practice of using larger fuses in the middle wire of open-delta banks than in the outside leads may seem peculiar at first glance, and a refinement not justified by the wide variation in fuse performance and the fact that current in the middle lead should ordinarily be only slightly greater than in the outside leads. Nevertheless, practice has shown that a decided percentage of middle-lead fuses have blown, and this change has seemingly improved service without jeopardizing the equipment to any greater extent.

The insulator-type primary cut-out ordinarily rated by the manufacturers at 30 amp., while having certain disadvantages, is nevertheless so attractive as to price that it is standard with nearly all companies for small 2300-volt installations. In higher-grade installations expulsion fuses are used for 2300-volt service over 30 amp., and even in some cases for 20-kw. or 25-kw. transformers. Oil switches should be used whenever possible for installations over 75 amp.

The positive advantages of oil switches, such as reliability of action, ease of resetting and protection against single-phase operation, should lead to a careful consideration of this protective device for all transformer stations of any considerable size and importance. The last feature is particularly important where stations serve large groups of small three-phase motors not equipped with low-voltage and overload releases. A case is on record where one 11-kv. station consisting of three 30-kw. transformers and furnishing energy to twenty-one agricultural installations of 5 hp. each operated single-phase after blowing a fuse, causing the burning out of seven of the motors.

Companies operating close to the coast or under other

severe conditions experience much difficulty due to the corrosion of the fuse links in the ordinary transformer plug cut-outs. This has been somewhat obviated by the use of fuses with copper terminals protected by asbestos sleeves. Under especially severe conditions this type of fuse holder must be mounted on an insulator to prevent breakdown to the cross-arm.

Standardization of fuse types is a necessity, since every trouble car must carry renewals for every type used on the system. At present when central stations are purchasing whatever brand of transformer the market affords without regard to contracts, it is particularly necessary to insist on a standard. Some plugs so nearly fit holders of foreign type that repairmen will be tempted to use them, yet they will often loosen, owing to vibration, or give trouble due to poor contact.

When companies use expulsion-type cut-outs troublemen should invariably be cautioned not to make fuses of larger size by twisting smaller sizes together. Many repairmen take it for granted that two 10-amp. fuses twisted together will make a 20-amp. fuse.

Fuses of the inclosed-cartridge type for voltages of 6600 and up, consisting of glass, porcelain, fiber or treated paper tubes, are best made up complete in the shop and issued to the troublemen properly tagged as to size. While space in the trouble kit can be saved by carrying a stock of fuse wire and filling powder, uniform care is not assured in making up the cartridge. For this type of fuse glass is to be preferred to fiber or treated paper. Although the most recent product of the latter type shows very little tendency to warp in the weather, nevertheless there is more opportunity for failure by leakage than with glass, and the fuse tube may catch fire after blowing, owing to a heavy "short." In one instance a grain field was set afire and the flames were extinguished only with difficulty; in another case a brush fire was started. While it is true that the

FIG. 2—FUSE INSTALLATION ON THREE-PHASE CIRCUIT

fragility of glass is a serious objection, nevertheless its qualities are such as to warrant its use until such time as a fireproof, non-warping, non-hygroscopic treated tube is produced.

A cheap grade of gage glass is ordinarily used for fuses of this type. Breakage is of course to be expected, both in transportation and under short-circuit

conditions, but in any case the renewal cost is moderate. A good 11-kv. to 22-kv. fuse of this type can be made, as shown in Fig. 2.

Combination fuses and switches are now on the market at very reasonable prices and are favorable for voltages of 11 kv. and up. They may be easily arranged for operation from the ground. There is an operating saving in such construction, since it obviates the neces-

FIG. 3—SINGLE-PHASE FUSE INSTALLATION AND DETAILS OF FUSE

The fuse consists of a gage glass $\frac{3}{4}$ in. (19 mm.) outside diameter by 17 in. (43.2 cm.) long with a $\frac{1}{4}$ -in. (3.2-cm.) wall. The ends are ordinarily corked; an aluminum fuse wire is brought out through a hole in the center of the cork and is soldered to a turned brass ferrule cemented to the end of the tube. A brass spring ferrule consisting of 0.08-in. (2-mm.) spring-brass wire turned up into a spiral of slightly smaller diameter than the glass may be used with a considerable saving over the solid ferrule. There is less metal and less labor in manufacture, placing on the tube and removal from broken tubes. In addition, attachment of the fuse wire is simplified. The end of the glass tube may be nicked with a file to obviate any possibility of the spring slipping off. The fuse wire should be doubled for the first few inches at each end of the tube so that it will be sure to blow well within the tube and also to assure good conductivity where the wire is most subject to injury. The end of the spring where the fuse wire is twisted around should be dipped in solder or, if a good aluminum solder is unobtainable, in compound to prevent corrosion.

sity of sending two men to renew a fuse, which would be advisable if the pole had to be climbed with the transformer "hot." With this equipment the renewal may be made with perfect safety by a single man, as the installation can be de-energized before the renewal is attempted. Furthermore, since the circuit is closed from the ground, there is no danger to the operator when a renewal is made under unsuspected short-circuit conditions. An added advantage of such an installation is that it permits an arrangement with the customer for cutting out transformers when service is not required, thus eliminating transformer losses.

Companies employing expulsion-type fuses mounted in wooden boxes will do well to give careful attention to box construction. Boxes which will not withstand the weather should not be used, because they will cause disastrous pole fires and line failures unless frequently inspected and repaired. A good box may be constructed of 1-in. (2.54-cm.) poplar painted inside with P. & B. and outside with three coats of a good pole paint. Boxes of this type are ordinarily constructed with one lead at the upper left side and the other at the lower right. This scheme may be improved upon by drilling an upper and a lower hole in each side of the box. The bushings and leads being readily removable, either upper hole may be used in conjunction with either lower. Thus four combinations are possible, and that which will give the neatest installation may be used in any case.

A typical single-phase installation is shown in Fig. 3, in which conditions are improved by using upper right-handle and lower left-handle holes on one side and

vice versa on the other. In some three-phase installations (Fig. 5) the best arrangement is secured by placing both bushings on the same side of the box. The practice of sometimes attaching the line wire to the upper and sometimes to the lower terminal should be discouraged, as this may lead to an accident. Where four holes are drilled in the boxes two pieces of sheet fiber should be sent out with each box to be used in closing the unused holes. This is necessary not only as a protection against the weather but also to prevent the entrance of birds. In this connection it may also be noted that if the bottom of the box contains a hole through which the expelled gas is blown, a wire screen covering should be used with a mesh small enough to exclude bees.

In installing boxes of this type they should be placed on the transformer arm and not above, and should be mounted on the back of the arm, so that they will be accessible to the troubleman without the necessity of passing by live apparatus. It is often advisable to use leads insulated for the full line voltage from the point where the main line is tapped to the transformer terminal. No. 6 seven-strand annealed copper wire with a 16/64-in. (6.4-mm.) 30 per cent Para rubber covering and single-braid and tape covering over all makes a good 11-kv. lead. Some troubleshooters do not understand that as long as one fuse remains in place pressure is maintained through the transformer windings, and consequently all transformer terminals are energized. This matter should be called to their attention.

A record of transformer fuse renewals is of considerable value in reducing transformer burn-outs and improving service. For this purpose a 3-in. by 5-in. (7.6 by 12.7-cm.) card of the form shown in Fig. 4 has been used with success by one company for a number of years. There are many cases in which the cause of the fuse blowing is never known. It may be taken for granted, however, that repeated blowing indicates an incorrect condition which should be investigated. This company having all transformer stations appropriately numbered files the record cards in numerical

order, and whenever three blown-fuse cards appear against one station within two years an investigation is made, particularly with reference to overload or defective customers' installations. The card also serves as a check on the installation of fuses of proper size.

Everybody Doing It—Buying Bonds

Light Projection with Gas-Filled Lamps

How the Lamps and the Optic System Used Therewith Have Been Sympathetically Developed So that It Has Now Become Possible to Make Satisfactory Use of Them for Motion-Picture Projection

BY R. P. BURROWS AND J. T. CALDWELL

Engineering Department, National Lamp Works of the General Electric Company

THE application of incandescent lamps to purposes hitherto served by carbon arc lamps has been considerably extended by the development of gas-filled lamps. The carbon arc for street and industrial lighting, and for nearly every application with the exception of projection, has been replaced by the incandescent lamp. For a time it was believed that the incandescent lamp would never replace the arc in projection lighting, especially as applied to motion-picture projection, because of its inherent limitations. The principal limitation was the relatively low intrinsic brilliancy of the source. If only the common types of incandescent lamps and the usual optical systems are considered, the limitation still holds. However, new incandescent lamp constructions and a sympathetic design of the optical system have made it possible to overcome obstacles that formerly existed. It is reasonable to expect that in a few years incandescent lamps will be as widely used in this field as in others previously dominated by the carbon arc.

Viewed from practical and commercial standpoints, optic projection has many complicated features. In the past the arc, the source most widely used for light projection, has been commonly, though incorrectly, considered a point source. Light projection with arc lamps has been accomplished with varying degrees of success, due chiefly to the high brilliancy of the arc and less to the efficiency with which the light is utilized. With gas-filled lamps the brilliancy is limited to about one-fourth that of a good direct-current arc, so the success with which the light is projected depends upon the utilization of the light. This is of the utmost importance in the use of gas-filled lamps for projection purposes.

An optical projection system may be divided into three parts and each considered individually, and then all considered collectively. They are the source of light (including mirror), the condensing lens, and the projection lens (or objective). They are related as follows: The condensing lens gathers the rays of light from the light source and redirects them through the image—film or slide—to be projected to the projection lens, which in effect enlarges the transparency on the screen. In general, the shorter the rear focus of the condensing lens (distance between lens and illuminant) the more light the lens will gather and redirect.

LIMITATIONS TO THE EFFECTIVE USE OF GAS-FILLED LAMPS

Limitations upon the efficiency of this operation follow:

I. Too short a rear focus will give too great a thickness of lens, which (a) increases absorption, due to its thickness and internal reflection; (b) gives poor definition, due to spherical aberration; (c) gives color, due to chromatic aberration.

II. Too short a rear focus will require light rays to strike the lens surface at too great an angle, increasing the surface reflection and causing a loss of light.

The light source may be considered from four viewpoints—brilliancy, size, construction and wattage.

I. Brilliancy.—Brilliancy is limited by (a) life of filament—the higher the temperature, the shorter the life and the greater the candle-power emitted per unit area of filament; (b) diameter of filament—in general, the greater the diameter of filament the higher the operating temperature for the same life.

II. Size of Source.—With condensing lens and projection lens given, there is an area of source which if increased will decrease the efficiency of utilization. It should be understood that a larger size of light source can be used, but that that portion of the source which

FIG. 1—RELATIVE POSITIONS OF GAS-FILLED LAMP, MIRROR AND CONDENSER FOR PROJECTION PURPOSES

The filament is wound in the form of four parallel helical coils lying in the same plane. The distance between the coils is slightly more than one-half the diameter of the coils. The lamp is designed for operation on circuits regulated for current rather than for voltage. It is made for operation with the tip end of the bulb uppermost, has a maximum over-all length of 10 in. (25.4 cm.), and a light-center length—the distance from the extremity of the base to the center of the light source—of 4 3/4 in. (12.2 cm.). The bulb is tubular and of such length that the fine particles given off by the filament are carried upward by the hot gas and deposited on a portion of the bulb well out of the zone of useful light. The rated average life is 100 hours. The mirror is backed with a heat-resisting material to withstand 125 deg. to 150 deg. C.

falls outside the dimensions determined by the character of the optical system is used much less efficiently than that falling inside the dimensions.

III. Construction of Source.—The construction or form of the source governs the distribution of light, which in turn limits the amount of light which can be used by the condensing lens.

IV. Wattage.—The wattage is limited by (a) size of light source; (b) construction of light source; (c) the diameter of filament.

The purpose of the projection lens (that nearest the screen) is to gather the rays which have passed through the film, redirect them to the screen and thus produce the size of picture desired. The larger the size of this lens, the greater will be the amount of light

projected, but the loss of definition and the high cost of large lenses of this kind limit the size to be used.

No doubt, the most radical change in lamp design, although not an entirely new development, is the use of the so-called "monoplane" type of lamp filament (Fig. 2), which is so arranged that all of the coils are in one plane, so to speak. This construction allows most of the filament to come within the focus area of the lens system to a much greater extent than obtains in the regular stereopticon lamps. In the latter the area occupied by the filament is greater and the coils, since they are not all in one plane, cannot all be close to the proper focus.

The light from the rear portion of the filament is gathered and redirected as useful light by a spherical mirror. The mirror is so placed that the filament is at the center of the outside radius of curvature of the mirror. With the monoplane construction images from the filament can be made to fall at points between the filament coils, thus giving a solid plane of light if the lamp and mirror are properly focused (Fig. 3). It is evident that to secure this effect with the stereopticon lamp filament would be impracticable, if not impossible.

Another characteristic feature of the new filament construction which is of great importance is the light distribution in a horizontal plane (Fig. 4). The light falls largely within angles at which the light can be utilized by the lens and mirror system. The advantages of such distribution should be evident.

It must not be inferred that the use of the monoplane filament construction is best adapted for all types of lamps for projection service. There are cases where some other type of construction may be used in order to obtain the size of source necessary.

It may be readily seen that if a large bulb were to be used to inclose the filament, advantage could not be taken of the short-focus condensing lens; consequently, it is necessary to use a bulb of as small a diameter as is practically possible. The size of bulb—that is, the area—is determined mainly by the wattage of the lamp. If the bulb can be made long and small in diameter—that is, tubular—the necessary area can be obtained with the advantage of the small diameter.

In obtaining concentration of filament it is necessary to get as high a wattage and filament brilliancy as possible for the size of light source previously determined. This can be most easily accomplished by the use of a large diameter wire, or, in other words, through the use of a high-current, low-voltage lamp. The high brilliancy of source desired is obtained by operating the filament at a higher temperature than is advisable for lower current lamps. At the same time, by the use of high current at low voltage, it is practicable to concentrate a higher wattage in the same size of source than if the lamp were designed to operate directly on 110-volt circuits. This low-voltage, high-current lamp is objectionable from one viewpoint, namely, that it cannot be used directly on regular lighting circuits. However, equipment can very readily be obtained for the operation of this lamp on lighting, power or isolated-plant circuits.

FIG. 2—MONOPLANE AND CONCENTRATED FILAMENT CONSTRUCTION

It has been found economical to burn the lamp at a high efficiency. It has also been found that where these lamps are used for long periods, say daily, as, for instance, where they are to replace the carbon arcs for motion-picture projection, the renewal cost on the basis of 100 hours' lamp life is comparable to the average cost of carbons, and though the cost of carbons may in certain cases be slightly lower, the reduction in wattage by the use of incandescent lamps with properly designed lens systems is such as to considerably more than offset this difference.

In order to utilize the maximum amount of light generated by the incandescent lamp, it is necessary to use a condensing lens with a short rear focus. The difficulties with this lens, as outlined before, were eliminated by the use of a prismatic lens of the Fresnel type (Fig. 1). This condenser utilizes a 76-deg. solid angle of light as compared to a 45-deg. solid angle with the arc-lamp condenser. The prisms are so designed and arranged as to make the condensing system as thin as possible and to distribute the light on the film so as to give an excellent "flat picture." The prismatic condenser is the most efficient condenser which can be used with gas-filled lamps at the present time, and it should be a part of every installation.

The correct operating positions of the lamp, mirror and condenser with respect to each other, with the various dimensions, are shown in Fig. 1. The spherical mirror performs two functions: (1) It utilizes the light from that portion of the filament farthest from the condensing lens, projecting the light back to the source and increasing the light on the screen from 50 to 75 per cent, depending upon the mirror used and the spacing between filament sections. (2) It fills in the space between the filament sections, thereby approximating a solid band of light.

METHODS OF INCREASING SCREEN ILLUMINATION

There is some uncertainty at present in the minds of theater managers as to how bright a motion picture should be shown. The tendency in the past has been toward brighter and brighter pictures, but to-day the trend appears to be toward pictures of moderate brightness. However, increased screen illumination can be obtained with gas-filled lamp equipment by the use of projection lenses with wider apertures. The wider the

FIG. 3—IMAGE OF FILAMENT FALLS BETWEEN COILS GIVING SOLID PLANE OF LIGHT

aperture of the projection lens—that is, the larger the diameter of the opening of the lens—up to a certain limit, the more light there will be projected on the screen. It has not been entirely possible to gain this advantage with the arc projection owing to the fact that as the diameter of the opening of the projection lens is increased the magnification of the arc lamp flicker is increased. The change from a projection lens

of F-2.5 to one of F-2* opening, of the same equivalent focus, increases the illumination on the screen by approximately 100 per cent.

In certain instances a two-wing shutter will give an increase in illumination and yet not increase the flicker. Two of the reasons for the use of two-wing shutters

FIG. 4—DISTRIBUTION OF LIGHT FROM MONOPLANE FILAMENT

are as follows: (1) With light sources which do not pulsate in intensity—for example, with gas-filled lamp and the direct-current arc—either shutter may be used. Flicker may occur, depending on the speed of film travel on screen surface with the two-wing, but the efficiency of light transmission is rather better than with the three-wing. (2) With pulsating light sources, such as the alternating-current arc, there is a possibility of a bad stroboscopic flicker of very low frequency if certain relations exist between the shutter characteristic and the alternating-current frequency. The customary 60-cycle service and the three-wing shutter constitute the most common example of an objectionable combination. Hence two-wing shutters are usually employed with alternating-current arcs, since the 32-cycle flicker of the shutter is less objectionable than the flicker caused by the stroboscopic effect.

The type of screen to be used in the theater depends to a large extent upon the length of throw and width of the theater or any extreme angles at which the picture must be viewed. Metallic and selective screens offer a picture brightness of from one time to seven times that of white paint and muslin screens for a projected beam of equivalent power. However, metallic screens are limited in their application to the narrow theaters in most cases. It is possible to project a satisfactory 12-ft. (3.7-m.) picture on a white paint or muslin screen. The width of the picture projected can be increased to approximately 13½ ft. to 14 ft. (4.1 m. to 4.3 m.) when a good type of metallic screen or ground mirror screen is used.

CONTROL APPARATUS FOR GAS-FILLED LAMPS

Twenty-ampere, 28-30-volt gas-filled lamps, like incandescent lamps for regular lighting service, operate equally well on either direct or alternating current, with no difference in the light output. The operation on alternating current may be at any commercial frequency.

On direct current a motor-generator set or rotary converter with proper control equipment and ammeters

is required to supply the lower voltage required by the gas-filled lamp. Of course, it is possible to use a resistance with a sensitive adjustment and an ammeter instead, but this method is not usually advisable because of the energy lost in the rheostat.

A transformer has been developed which can be used on 110 120 volt and 220-volt alternating-current circuits. This transformer includes a variable resistance, or a reactance, in the primary circuit to take care of the variations in line voltage, thus enabling the operator to maintain the normal current on the lamp. An ammeter is placed in the secondary circuit of the transformer, and a four-point starting switch is included in some equipments. This switch eliminates the possibility of a rush of current through the cold lamp when the current is first applied, for the connections are such that the current is gradually increased as the switch is turned from the "off" to the full-current position.

For use with the present arc-lamp transformers a panel attachment has been developed, which includes a rheostat for regulation, an ammeter, a reactance coil and the four-point starting switch.

At the present time there are on the market a number of transformers which are being used with the 20-amp. gas-filled projection lamp, but which are not recommended, although they are cheaper than the transformer mentioned above. They do not contain a variable resistance in the primary circuit to take care of fluctuation in the line voltage, nor do they include an ammeter. Thus the operator is not in a position to know whether his lamp is burning at, above or below normal current, which is very important with gas-filled lamps. In order to take advantage of all the light possible, the filament is operated at a temperature close to the melting point. Any marked increase in current delivered to the filament materially shortens the life of the lamp, and any decrease in current delivered to the lamp is followed by a loss in light on the screen.

ADJUSTMENT OF LAMP, MIRROR AND CONDENSER

A number of things must be done in order to place the lamp and mirror in the correct operating position. First, it is essential that the plane of the four parallel coils of the filament be perpendicular to the optical axis, which is an imaginary line drawn through the center of the screen, the projection lens, the aperture plate, the condenser, the lamp filament and the mirror. To obtain this condition the lamp should be put in the

FIGS. 5A AND 5B—FILAMENT ALONE AND FILAMENT WITH IMAGE BETWEEN COILS

relative position determined by the dimensions, then moved horizontally and vertically until the image of the filament coils can be seen very distinctly on a piece of white cardboard or paper held against the shutter wing in front of the projection lens (Fig. 5A). Then the mirror should be inserted, making the proper ad-

*This term is obtained by dividing the equivalent focus of the projection lens by the diameter of its free opening.

justments so that the mirrored image of the coils appears on the card as distinctly as possible in the spaces between the direct image of the coils, which is also on the card (Fig. 5B). Extreme care should be taken to avoid focusing the mirrored image over the direct image.

From the above discussion it will be noted that gas-filled lamps can be used for motion picture projection to the fullest advantage only when installed in connection with the proper mirrors, special condensing lens and good regulating equipment. The authors claim that, in general, wherever alternating-current arcs are at present in use the 20-amp. gas-filled lamp will, when properly installed, project pictures equal to or better than the arc lamp, with a considerable saving in operating cost. Furthermore, it can replace direct-current arcs rated up to 35 amp. and may be used for either motion picture or stereopticon projection work. A satisfactory picture can be projected with gas-filled lamps with a throw up to at least 90 ft. (27.4 m.). The permissible width of the picture to be projected will, of course, be affected by the character of the screen used. As previously mentioned, the type of screen and rating of the projection lamps used play an important part in obtaining the most satisfactory and largest picture which can be projected with this lamp.

In the past it has been the usual practice to endeavor to obtain the maximum screen illumination in projecting motion pictures, but the tendency at the present time is to decrease the screen illumination to a point where eye fatigue is entirely eliminated. The fatigue is caused by the sharp contrast between the white portion of the pictures and the darkness of the theater.

The intensity of the projected beam determines only the relative brightness of the picture. This may be understood when the different classes of screens are considered. The three common types of screens in use to-day are the matte screen, the metallic surface screen and the mirror screen with a ground surface. The percentage of illumination reflected by the above screen depends upon the type or surface of the screen.

The transmission efficiency of the various tinted and toned films in use to-day reduces to a certain degree the glare which would otherwise result from the high intensities if black and white films were used entirely. The tinted and toned films give a soft picture but absorb considerable light, about 20 per cent for light tinting and up to 80 per cent for some of the deep reds.

The screen illumination produced by gas-filled lamps is very uniform. There is neither travel of the light source nor source flicker, as in the case of the arc. The color values of the light from the incandescent lamp are desirable. Gas-filled lamps are entirely inclosed in metallic housings so that the heat is confined and the booths kept comparatively cool. Trouble with carbon dust deposits on the condensing lens is also eliminated. The reduction in operating expenses has been previously mentioned; the average renewal cost is slightly lower and the wattage required is much less. There is a further saving in the elimination of the warming-up process with its requirement of overload capacity. In fact, the simplicity of the gas-filled lamp is a feature which appeals to the operator. Once the lamp is placed in the projection machine, it requires no further attention from the operator until it burns out.

POTENTIAL GRADING ON SERIES LIGHTING CIRCUITS

Tests on Circuits in Chicago Park—Lighting System Shows Advantages of Operating Series Circuits Ungrounded

TESTS to determine the potential gradient and the location of the electrical center on a series street-lighting circuit with its last lamp 6 miles (9.6 km.) from the switchboard have been made by engineers of the electrical department of the Lincoln Park Commission under the direction of C. H. Shepherd, electrical engineer in charge. The circuit investigated consists of the following: One 37.5-kva., single-phase, 60-cycle, 12,000 2000 5000-volt Moloney transformer regulated by a 50-lamp Western Electric induction regulator rated at 7.5 amp. with the necessary "disconnects," oil-switch, instrument transformers, etc.; 104 gas-filled tungsten lamps rated at 400 cp., 15 amp.; two Kuhlman series-multiple 7.5 15-amp. transformers; 102 Westinghouse 7.5/15-amp. compensators; 63,360 ft. (about 19,500 m.) of No. 6 solid single-conductor paper-insulated lead-covered cable and 8440 ft. (about 2400 m.) of No. 6 solid single-conductor rubber-insulated triple-braided cable. The total length of the circuit was 71,800 ft. (about 21,900 m.). The inherent power factor of the compensator was 97.5 per cent, and the inherent efficiency of this unit was 93 per cent. The power factor and efficiency of the transformer were respectively 99.5 per cent and 94 per cent. The lamps are staggered on the cable, and both legs of the circuit are run in the same type of non-magnetic conduit.

Tests were first made in the station by placing grounds at different points with the following results: With a ground at the station on the left leg of the circuit the pressure across the circuit was 2840 volts. With the ground at the station on the right leg of the circuit the pressure across the circuit was 3440 volts. The potential across the circuit with no ground on the circuit was 3540 volts; the potential to ground on the left leg of the circuit with no ground on the circuit was 1760 volts, and the potential to ground on the right leg of the circuit with no ground on the circuit was 1740 volts. These data showed that with one end of the circuit grounded at the power house the potential to ground was approximately 100 per cent greater at the other end than when the circuit is operated ungrounded.

Readings of potential from the line to ground were then taken at each lamp and showed that the potential gradually increased from 50 volts at the center of the circuit to 2160 volts to ground on the left and 2140 volts on the right leg of the circuit. These readings were taken without the line being grounded. The readings seemed to indicate that the end of the physical center of the circuit was also its electrical center. The circuit was then grounded at its physical center with a 15-amp. ammeter in the ground connection. The ammeter showed 2 amp. flowing to ground.

Readings taken from the line to ground with the line grounded showed that the electrical center of the circuit shifted and that the potential to ground increased at practically all points along the line. The potential across the circuit at the switchboard was 3500 volts, and the highest potential to ground proved to be at the switchboard, where the value was 2160

volts. At the lamp nearest the power house, which was practically 3 miles (6.4 km.) distant, the potential to ground was 1900 volts.

Curves plotted from the readings taken in these tests are shown in the accompanying curves. By reference thereto it will be seen that the potential gradient is almost uniform. This is due to the fact that there was during this test no ground on the circuit, allowing the neutral point to shift its position to compensate for changes in reactance on the circuit due to lamp burn-outs, regulator movements and electrostatic conditions throughout the entire length of the circuit. The curves also show that with the apparent electrical center of the circuit grounded the potential gradient is unbalanced and not uniform owing to the fact that the neutral point is fixed by being grounded. Flexibility

VOLTAGE FROM SERIES CIRCUIT TO GROUND AT DIFFERENT POINTS UNDER DIFFERENT CONDITIONS

and freedom of adjustment of the ungrounded circuit in response to changes of electrostatic and electromagnetic conditions are thereby seriously hampered. The unbalance due to action of the regulator and to changes in electrostatic capacity due to variations in the specific inductive capacity of the various dielectrics used along the circuit are plainly apparent.

It was expected that the introduction of a ground at the apparent neutral point where a potential of only 50 volts to ground existed would reduce the potential at that point to zero and accordingly reduce the potential to ground all along the circuit. The ground was not placed at the electrical center, however, because the reading at the supposed middle lamp rose from 50 volts to 199 volts, while the potential to ground at a lamp three posts from the supposed center fell to zero. The maximum potential to ground on the circuit with the ground connection in place rose by amounts varying from 20 to 60 volts at different points. This apparently showed that grounding at a definite point does not reduce the maximum potential to ground, owing possibly to electrostatic conditions.

Grounding does, however, make it easy to locate trouble. With a ground at the electrical center of the circuit, it is apparent that should another ground occur on the circuit the lamps between the two grounds will

not burn. It would be very easy, therefore, to locate the second or accidental ground which is the cause of the trouble.

In another test conducted in order to get an idea of the relative value of the induction and capacity of the circuit the cable was opened at its physical center. A potential reading at this point showed a value of 4500 volts across the ends of the circuit. Readings to ground were then taken at each lamp with the circuit open at its center. While this test was in progress trouble developed on the circuit at a little over 3000 volts, showing that at this low potential to ground a breakdown is possible under open-circuit conditions. The exact voltage conditions causing the trouble were not determined at the time because of lack of instruments. To all appearances, however, a great rise of pressure occurred, possibly due to a condition approximating resonance.

While further investigation of these conditions on the park circuits is still in progress, certain conclusions appear evident at present: First, better voltage conditions, less dielectric strain to ground and greater flexibility of adjustment appear when operating the circuit ungrounded. Second, grounding the apparent electrical center causes no apparent release of electrical strain nor decrease of pressure to ground, but on the contrary impairs the uniformity of the potential gradient and causes an unbalanced condition. Third, the advantage of quickly locating a ground made possible by a grounded electrical center is outweighed by the disadvantages caused by grounding, because a ground can always be placed on a circuit at the station quickly. Fourth, the practice of grounding one end of the circuit evidently makes a large increase in the dielectric strain to ground at the other end of the circuit. On the whole, it is thought the ungrounded circuit offers greater advantages than any system of straight grounding as far as operating conditions are concerned.

STATUS OF NON-WAR PROJECTS

War Industries Board, in the Public Interest, Will Discourage All Such Enterprises

Calling attention to the organization of new industrial corporations in different sections of the United States for non-war manufacturing and to the plans being considered by certain states, counties, cities and towns for construction and other improvements not contributing toward winning the war, the War Industries Board has passed a resolution indicating a firm attitude toward such projects. The resolution concludes:

That in the public interest all new undertakings not essential to and not contributing either directly or indirectly toward winning the war which involve the utilization of labor, material, and capital required in the production, supply or distribution of direct or indirect war needs will be discouraged, notwithstanding that they may be of local importance and of a character which should in normal times meet with every encouragement.

That in fairness to those interested therein notice is hereby given that this board will withhold from such projects priority assistance, without which new construction of the character mentioned will frequently be found impracticable, and that this notice shall be given wide publicity, that all parties interested in such undertakings may be fully apprised of the difficulties and delays to which they will be subjected and embark upon them at their peril.

New Bedford Company's 52,000-Kw. Station

Engineering Features of Steam Turbine Plant Which Supplies Textile District with Power and Is Interconnected with Other Utilities in Buzzards Bay and Cape Cod District

OWING to the difficulty of securing coal and the shortage of capital for industrial development, many textile plants in New England have been attracted to the use of central-station energy. In the Feb. 23 issue it was pointed out how these conditions have put an unusually heavy demand on the New Bedford Gas & Edison Light Company, which has endeavored to meet it by building a new 52,000-kw. steam station. Some of the factors which influenced the location and design of this plant were outlined, and engineering features of the coal-handling and boiler-room equipment were discussed. This article will dwell on the remaining mechanical and electrical features.

PIPING ARRANGEMENTS, COOLING OF BEARINGS AND BOILER-ROOM INSTRUMENTS

Two 5000-hp. feed-water heaters are in service, each having a capacity of 150,000 lb. (66,035 kg.) of water per hour, with a range of temperature of 40 deg. to 210 deg. Both heaters are mounted on a gallery between the boiler-room and turbine-room walls, one heater being of Hoppes and the other heater being of Cochran make. The feed-water piping is of semi-steel and is installed in duplicate to insure maximum flexibility of service. The feed-water supply is taken from a discharge well into which the condensate is delivered, make-up water coming from the city mains, which enter the premises by two lines, on opposite sides of the property, with cross-connections between. Copes feed-water regulators are installed.

A portion of the water from the hot well is circulated through the bearings of the turbo-generators instead of relying entirely upon city water for this service, thus securing a decided economy in the consumption of the latter. After leaving the bearings the water is returned to the hot well, from which it is drawn into the feed system of the boilers. The feed pumps consist of four Terry turbo-driven Janesville units, rated at 250, 350, 500 and 1000 gals. (946.3, 1324.8, 1892.6 and 3785.3 l.) per minute respectively. A service pump of the same make, driven by a 15-hp. Terry turbine and capable of handling salt water at the rate of 200 gal. (257 l.) per minute, is also provided for wetting down ashes and for lavatory supply. This, with a Westinghouse locomotive-type air compressor for general service, is installed in the basement of the boiler house near one of the forced-draft fans.

Each boiler is equipped with a General Electric steam-flow meter of indicating and recording type, two Ellison draft gages showing conditions above and below the fire, an indicating steam-pressure gage, Foxboro steam-pressure and temperature recorder, a Hohmann & Maurer indicating flue-gas thermometer, and two Bailey feed-water flow and temperature recorders, one for each heater. A Lee V-notch meter is provided for checking the feed-water measurements.

Each pair of boilers delivers steam into an overhead cross line which joins a horizontal main running par-

allel to the fire-wall separating the boiler and turbine rooms, the main being supported on saddles about 36 in. (91.4 cm.) above the boiler-room floor. Ample provision has been made for expansion loops. Long-radius curves are provided in the piping between boiler batteries and in the risers which take the steam from the main to the various generating units. Instead of running a separate steam line to each of the 4000-kw. units a single branch or steam bus is run from the main across the turbine room at right angles to the axes of these generating sets, a short connection being made with each.

This arrangement sectionalizes the turbine piping, giving the station one main live steam connection for each unit of 10,000 kw. rating or more, and avoiding

FIG. 1—CONDENSER AUXILIARIES ARE SITUATED IN PIT AT RIGHT

the use of a greater number of small-capacity steam leads into the turbine room. From the steam-supply standpoint, therefore, the three smaller turbines may be treated as a single unit, although each machine is provided with an individual stop valve between the branch main and the turbine inlet. Blind flanges are left in the cross steam connections leading to the main for the attachment of feeders from boilers on the opposite side of the firing aisle as the new boilers are added.

The condensing water tunnels run under the turbine-room basement, the intake, discharge and air duct leading to the generator being combined in a single reinforced-concrete structure. Cleaning of the screens is accomplished by raising sections out of the grooves in which they are seated, the lifting being accomplished by a 1-ton Sprague traveling electric hoist, which runs above the screen bulkhead. A small shelter is provided at one end of the crane runway to house the hoist when

it is not in service. The circulating water is drawn from suction wells built into the station foundations.

All of the condensers are of the surface type, the 10,000-kw. and 15,000-kw. units being Worthington equipment supported on springs with copper expansion joints. At the time when the 10,000-kw. turbo-generator was purchased it was felt that the Worthington

2800 r.p.m. on the auxiliary turbine to 460 r.p.m. at the pump shaft.

The condenser for the 10,000-kw. unit has a capacity for liquefying 130,000 lb. (59 kg.) of steam per hour, the capacity of the circulating pump being 19,000 gal. (71,921 l.) per minute against a head of 24 ft. (7.3 m.). Provision is made for 15 per cent speed regulation in

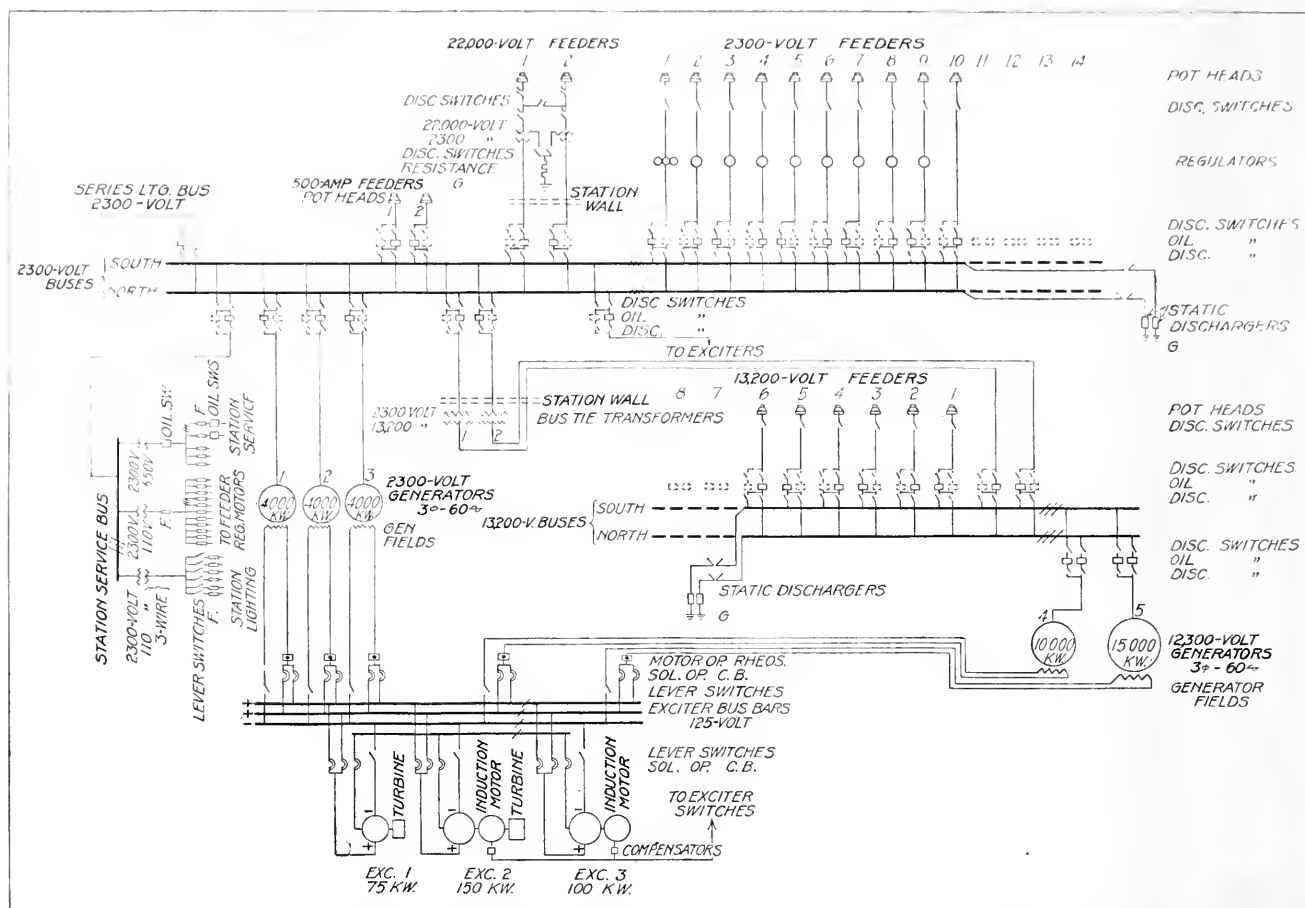

FIG. 2—LARGE GENERATORS ENERGIZE 13,200-VOLT BUS AND SMALLER GENERATORS FEED 2300-VOLT BUS, THE TWO BEING CONNECTED BY BUS-TIE TRANSFORMERS

hydraulic air pump was in the development stage, so a Laidlaw-Dunn-Gordon reciprocating dry-air pump was provided for this unit and the first 15,000-kw. set. The second 15,000-kw. unit will be equipped with a Worthington hydraulic air pump of the centrifugal type, however, as will also one 4000-kw. unit. These pumps are much more compact than the reciprocating type and permit the use of steam-turbine drive, which eliminates oil in the exhaust steam. Maintenance is reduced as compared with a reciprocating pump, and the number of working parts is less. While nearly twice as much steam is required as with a reciprocating pump, the utilization of the exhaust with an efficiency of about 80 per cent makes the actual consumption of steam of minor importance.

Two of the 4000-kw. turbines are equipped with Alberger surface condensing sets transferred from the old station. All of the circulating pumps are driven by Terry turbines. Worthington hot-well pumps are provided with the later units. By the use of Falk reduction gears for driving the centrifugal circulating pumps higher turbine speeds are obtainable, resulting in approximately 50 per cent increased auxiliary steam economy. A representative speed reduction is from

this pump. The 15,000-kw. units are equipped with circulating pumps having a rating of 25,000 gal. (94,663 l.) per minute each. Each condenser has a capacity of 190,000 gal. (719,213 l.) per hour. Each of the smaller turbines requires about 8400 gal. (3179.7 l.) of circulating water per minute.

Each main generating set is equipped with the following instruments: Hohmann & Maurer mercury column vacuum gage, Ashcroft steam-pressure indicator and vacuum indicator, first-stage steam-pressure indicator and a General Electric speed indicator reading in terms of frequency. A 110-volt lamp-signal system is in use at the various units and is connected with the switchboard.

GENERATING UNITS

All the generating units are General Electric three-phase alternators driven by Curtis horizontal turbines. The three 4000-kw. units are wound for 2300 volts, the larger generators for 13,200 volts. There are two General Electric-Terry exciters of the combination motor and turbine-driven type, rated at 150 kw. and 200 kw.; one 100-kw. motor-driven exciter and one 75-kw. turbo-exciter, all wound for 125 volts. It is planned to stand-

ardize the use of combination exciters. A spray air-washer installation with a capacity of 50,000 cu. ft. (1400 cu. m.) of air per minute is installed to treat the ventilating air. Another set will be provided shortly.

The turbine room is served by a 50-ton Northern four-motor electric crane which has a 5-ton auxiliary hoist. The bridge speed is 175 ft. (53.3 m.) per minute, the trolley travel 100 ft. (30.4 m.) per minute, the main hoisting speed 6 ft. (1.8 m.) per minute, and the auxiliary hoisting speed 30 ft. (9.1 m.) per minute. The crane serves all the larger auxiliaries in the turbine room. A standard-gage railroad track enters the room on the ground level to facilitate handling heavy machinery while another track entering the room on the south side permits moving transformers into the building when they have to be repaired or inspected.

The electrical bay of the station is four stories high, the operating switchboard being on the third floor and completely shut off from the turbine room by a fire wall. The general arrangement of electrical layout was shown in Fig. 1 of the first installment of this article. The electrical bay provides for more feeders, switches and other electrical apparatus than the hydro-electric plant of the Mississippi River Power Company at Keokuk, Iowa, where the installed capacity in generators is nearly three times that of the New Bedford installation now under contract. This is due to the difference in service requirements.

Special effort has been made in this plant to isolate each switch and bus section from others. Every oil switch is housed in a reinforced-concrete compartment of sufficient strength to localize the effects of an explosion in the switch to that particular cell. The street-lighting equipment is also isolated; voltage regulators on the commercial lighting feeders are separately located and confined, and the 2300-volt and 13,200-volt

room enabled short runs of cable to be used between the exciters and the exciter buses, and from the latter to the generator fields. On the second floor are the switches and buses of the 13,200-volt system. The third floor contains the main operating switchboard, street-lighting switchboard and rectifier sets and local testing apparatus, and the fourth floor is devoted to 2300-volt buses and oil switches. Feeder regulators are installed on the third floor, in fireproof compartments separated from the main switchboard. These are conveniently situated where they can be connected with the 2300-volt system, the cables being carried down the north wall of the electrical bay from the bus and oil switch compartments to the underground conduit system.

Investment in duplicate selector-type oil switches has been avoided for the time being by the use of cross-connecting leads between each oil switch installed for feeder service and the appropriate terminals of the disconnecting switches placed between the oil switch and the buses. The cells are installed in the switch structure so that ultimately each feeder switch can be connected by remote control with either bus. For the present, however, only one oil switch is provided per feeder, selection of buses being made by knife switches. No feeder can be connected to a bus when the oil switch is open, and each feeder can be isolated from both buses by opening the oil break switch. The same arrangement prevails in connection with the oil switches used between the bus-tie transformers and the 2300-volt and 13,200-volt buses. The bus-tie transformers, of which there are six, are 1500-kva. General Electric oil-cooled transformers supported on rollers outside the station, as illustrated. The bus structure is supported on steel framework, the cables being carried thereto from the corresponding buses in the electrical bay through ducts and vertical concrete structures shown in

FIGS. 3 AND 4—MAIN SWITCHBOARD AND VIEW OF OIL-SWITCH AND BUSBAR COMPARTMENTS

bus systems are entirely separated. Furthermore, each of these systems has duplicate buses which are separated from each other by vertical fire walls.

The exciter switchboard and field rheostats are installed on the south side of the station just above the street floor and under the offices of the chief engineer. Installation of this apparatus outside the switchboard

the illustration. The latter are to prevent persons coming in contact with the high-tension cables where they rise to the outdoor bus structure.

The 22,000-volt line radiating from the station is fed through six 750-kw. General Electric oil-cooled transformers installed in the same row as the bus-tie sets. They are connected with the 2300-volt busbars

on the low-tension side. This line is operated, Y-connected, with the neutral grounded through a resistance installed in a fireproof house at the end of the transformer banks.

The main switchboard, containing twenty-seven panels, is provided with remote-control connections to all oil switches, control energy being supplied by a sixty-cell battery furnished by the Electric Storage Battery Company. General Electric type H-3 motor-operated oil switches are installed in connection with both 2300-volt and 13,200-volt buses. The disconnecting switches are arranged for locking in position. All generating units, bus-tie lines, feeders, exciters and trans-

FIG. 5—BUS-TIE TRANSFORMERS WHICH ARE CONNECTED WITH BUSBARS INSIDE STATION BY CABLES LEADING DOWN CONCRETE DUCTS

formers for outside service are controlled from the main board. Dummy buses are not installed, they being considered unnecessary with this arrangement of panels and controls. The central location of the main board resulted in a saving of considerable control wire, with switch structures above and below. The control battery is charged by a 5-kw. General Electric motor-generator set in the switchboard room. From this room 22,000-volt open-air switches on the line side of the transformers, serving Lakeville and the territory at the east of New Bedford, may be opened by mechanical handling of rods and levers carried down the side of the building to the transformer bus structure.

W. H. Snow is manager, D. W. Beaman general superintendent, and R. H. Barber chief engineer of the New Bedford company.

Win-the-War Spirit in Business Letters

"See that a win-the-war spirit gets into your business letters" is the slogan of a movement launched by the Department of Commerce to remind business men that the every-day business letter is a most effective instrument for creating confidence in the government's war policies and inspiring others.

COLLECTING STATISTICS FROM CUSTOMERS' ACCOUNTS

Use of Tabulating Machines for Quickly Determining Vital Data Regarding Growth, Income, Rates, Etc.

BY G. R. KENNY

San Joaquin Light & Power Corporation, Fresno, Cal.

SINCE April, 1917, the San Joaquin Light & Power Corporation has used the Hollerith tabulating machine to compile statistics on accounts of light and power consumers. This company and the Midland Counties Public Service Corporation, with headquarters at Fresno, supply electric energy to consumers in five counties in central California. The population of the territory served is approximately 200,000. In November, 1917, the two companies were serving 26,657 lighting consumers and 3724 power consumers. The total connected load in power was 58,717 hp. Several large consumers who purchase power at wholesale rates for large industries, or for redistribution, are considered as power consumers, and the capacity of their transformers is included in the connected load above. The main transmission is at 60,000 volts and 30,000 volts, with distribution from thirty-one substations. During the year ended with November, 1917, 119,576,947 kw.-hr. were distributed from the substations.

Power consumers are served at uniform non-discriminatory rates, the principal types in use being the "block," "demand and energy" and the "Wright" forms of schedules. Flat rates per horsepower of demand are in use for irrigation pumping business. A straight kilowatt-hour rate is used for some of the oil-well pumping. Demand indicators are used to determine the demands in most cases. "Block" and "demand and energy" forms of rates are in use for lighting service.

Light and power consumers' accounts are kept in separate ledgers in each of the thirteen districts served. For the city and town service the consumers' ledger sheets are arranged in street-number order, the name being changed in case one consumer moves out and another moves in. In case a consumer moves out and it is probable that another will move in within a reasonable time, the meter is sealed and left on the premises. The ledger sheet is removed from the ledger where buildings are changed or the street-number order is otherwise upset. Each ledger sheet is arranged to carry a consumer's account for a period of two years and also for recording meter data and other necessary information.

One Hollerith sorting machine and one five-bank tabulator are installed in the Fresno office, and a key punch is supplied to the consumers' department in each district. The cards are punched by the consumers' department after the first of each month with the data for the previous month. One person can punch from 800 to 1200 cards per day. This work is done by regular employees in the consumers' departments.

When the system was installed each ledger sheet in each district was "coded" with the code numbers applying to it. Any changes in code are made on the ledger sheets when the information which makes the change necessary is recorded on the sheets.

A code which gives the size and voltage of single-

phase and polyphase meters, and the constant in use, if any, is entered on the ledger sheet, and the number appearing on each sheet is punched in the meter data column of the card for that consumer. Nine hundred and ninety-nine combinations are possible in this code, but only about 300 are in use. The even numbers are used for regular installations, and the next odd number if a demand indicator is installed. As an example No. 2 indicates a 5-amp., 110-volt watt-hour meter, but if a demand indicator were installed No. 3 would be entered on the ledger sheet. To each account or ledger sheet a number is given, and the "service" is divided under light and power.

The principal codes provided outside of the meter data are the "occupied as," under which the business is divided into fifty-one classifications, as "residences," "drug stores," "saloons," "restaurants," "agricultural consumers," "oil production consumers," etc., and the "rate schedule code," under which each rate schedule is given a specific number. These code numbers are entered on the consumers' ledger sheet, and do not vary unless there is some change in the installation or the business.

A "new or old" code is provided to show present consumers, business disconnected during the month, and new business connected. The "minimum" code covers the several classes of minimums in use by the company, and is used only when a consumer is billed on a minimum. The maximum demand, consumption and amount of bill are entered each month on the ledger sheet, but the connected load is changed only when a change is made. The information regarding connected load in power is accurate, but it is very difficult to keep accurate record of the connected load of lighting consumers, owing to so many changes being made without the company being notified.

METHODS OF COLLECTING AND TABULATING INFORMATION

When the system was put in operation all ledger sheets were "coded." The code number is changed if changes are necessary, and all new ledger sheets are "coded" when placed in the ledger. The key-punch operator punches the month, year and service automatically, and finds the account number, district number, "occupied as," rate schedule and meter data codes, and connected load on the upper part of the ledger sheet. The maximum demand, consumption, amount of bill, and the new or old minimum codings, are taken from the monthly entry in the ledger. One card is punched for each sheet, a special "new or old" code number being provided for dead sheets. The codes are then checked and sent to the general office. The total earnings are taken directly from the ledgers, proved, and reported in totals in advance of the cards being punched. As soon as the cards arrive at the general office they are run through the tabulating machine and the total earnings taken. This must agree with the earnings already reported. If not, the adding machine tapes are sent in and the cards checked against them. If the earnings in dollars and cents agree it is assumed that all other data contained on the cards are correct. The cards are then run through the sorter to eliminate dead accounts, company business, cut-outs and adjustments. The remaining cards represent active consumers for the month. The eliminated cards are tabulated for all information contained on them. The

active cards are run through the sorter and segregated according to rate schedules, then put through the tabulator, which counts the cards and sums up the connected load, maximum demand, consumption and amount of bill. This information is recorded by rate schedule and by districts by the operator and sent to the statistical department, where the information is entered in special books provided for that purpose, and statements showing the monthly system totals are made up. This information is entered so that annual totals can be taken by adding across the sheets. In the same manner the "occupied as," meter data, and new or old reports, are then made.

Statements of number of consumers, consumption, connected load, maximum demands, earnings and average earnings per consumer, per kilowatt hour and per horsepower, for power, are prepared by rate schedules and by classification of business under the "occupied as" code each month. A statement of earnings by districts, and the number of light and power consumers added or lost by districts, is prepared and a "meter report" made up.

USE OF INFORMATION

The information is used to show the income from various classes of business, in studying the past growth of the business and estimating future growth and requirements, in determining which classes of business are most profitable, in studying the effect of rates, and in making new rates and changing existing schedules. As an example of the use in "rate making," the income from a given block rate may be accurately predetermined if the consumption in each block is known. This information can be quickly assembled by sorting the cards according to consumption and tabulating by kilowatt-hours used, either by all the amounts used, from zero to the maximum, or by the blocks which are to be applied. Before this system was installed it became necessary to assemble this information, but it required three months for two men to tabulate the information for 3000 consumers over a period of twelve months. A sample run indicates that this information can now be assembled for a twelve-month period on 26,000 lighting consumers in about six days.

About forty days' total time is necessary to punch and check all cards. One person operates the machines and one tabulates the information and makes the regular statements for 30,000 consumers. Ordinarily, but two or three days' time is required to punch and check the cards in each district, nine days being necessary for the largest district with over 10,000 cards. At the present time it takes about twenty-five days' time for the Hollerith machine operator to run the cards, and twenty days' time for a clerk to assemble the information and make the statements each month. The monthly reports are all prepared and out by the end of the following month. The work has been slow on account of many changes and lack of help in the districts. Under normal conditions the districts would be able to punch their cards, and the information could be tabulated and each month's statements made and out by the 20th of the following month. It is the intention to extend this scheme to give similar information for about 7000 gas consumers and 9000 water consumers. All of this work can be handled by the present machine and the present force.

STATION & OPERATING PRACTICE

A Department Devoted to Problems of Installation, Operation and Maintenance of Equipment for Economical Generation and Distribution of Electrical Energy

WOOD SHAVINGS USED FOR FUEL IN A POWER PLANT

Plant Shutdown Averted by Their Use During Coal Shortage—Description of Conveyor Utilized for Handling Shavings

The Missouri Public Utilities Company of Poplar Bluff, Mo., is using wood shavings from a nearby wagon-spoke factory for fuel. As the factory is about 2000 ft. (609 m.) from the power house, it was at first considered advisable to convey the shavings to the plant by means of a pipe line equipped with blowers. It was found impossible to do this on account of the character of the shavings, which were of the long hard wood type. The shavings therefore have to be hauled to the plant by wagons and are dumped into a storage shed. A flight conveyor carries the shavings to the boiler room and drops them into conveyor pipes which lead to the furnaces. Shavings swept past the pipe openings are caught by a chute and dropped into a cage mounted on a wheelbarrow. They are then wheeled back to the storage shed at frequent intervals.

In order to fire the shavings in combination with coal the furnaces, which formerly burned coal alone, had to be redesigned. It was decided to extend the furnace fronts to give a Dutch oven effect. When the furnace fronts were extended it was possible for the conveyor tubes to drop the shavings directly over the middle of the fires. It has been observed that the efficiency with shavings is greater than that with coal alone because coal cannot be thrown far enough back into the furnace to give the best results. Under the present method of operation, coal is shoveled into the furnace in conjunction with the shavings, as the supply of shavings varies with the output of the wagon-spoke factory. During the recent severe winter it was impossible to obtain coal, and had it not been for the availability of the shavings the plant would have been compelled to shut down for lack of fuel.

Liberty Calls—Lend to Protect It

MOUNTING MOTOR-GENERATOR SET ON THE STATION WALL

Simple Arrangement Afforded and Less Space Occupied by This Unusual Installation of Battery-Charging Outfit

In a New England hydroelectric plant space limitations made it desirable to mount a small motor generator set, used for storage battery charging, off the floor and at low initial cost. Accordingly the machine was attached to the station wall, as illustrated, on a vertical base bolted through to the outside of the building. With all wiring carried in conduit and the controlling switch, relay and watt hour meter for this service

mounted on a marble panel about 3 ft. (0.9 m.) from the motor-generator, an unusually simple arrangement, free from danger of injury to circuits, carried well above the flood line of the stream and affording a clear floor for station cleaning, is obtained. The front

PUTTING MOTOR-GENERATOR SET OUT OF MOPPING ZONE

of the unit does not extend beyond the clearance plane of the switchboard equipment on the front of the panel, and thus the set forms no material obstruction to movement in the operating room.

Your Money Helps to Save Liberty

FIVE-WIRE SUPPLY FOR BIG ELECTRIC FURNACES

Distribution of Heat in Large Furnaces Can Be Effected by Making Use of Four Electrodes and a Neutral

In a paper entitled "Electric Steel-Refining Furnaces" presented before the Faraday Society recently J. Bibby said that while two electrodes may be sufficient for small furnaces up to 5 tons capacity, it is not advisable to concentrate the heating zone in larger furnaces in two places. Another reason why more than two electrodes are required in large furnaces is because the electrodes at present available cannot carry more than 10,000 amp. each.

Whatever system is adopted it must be such that when equal currents are flowing through each of the arcs, then equal currents must be taken from each of three high-tension mains, and each of these three primary currents must be practically in phase with its voltage in order to secure a high power factor. Further, for metallurgical reasons it is considered desirable that a certain amount of current should flow vertically through the hearth to a fifth fixed electrode beneath it. Therefore some system is required which will impress an equal voltage between each upper electrode and the hearth electrode and give four equal heating zones.

The condition is met if four equal phases can be obtained on the furnace side of the transformers—one for each electrode and a common return to a neutral electrode beneath the hearth. In short, a four-phase, five-wire system is required. This can be obtained by having two sets of two phases working in parallel, but this system has serious electrical objections. The problem has been satisfactorily solved by using a four-phase arrangement, which involves three single-phase transformers. Two of the transformers have their terminals connected separately to the four upper electrodes. A tap is taken from the middle of the third or teaser transformer to the hearth electrode, and the terminals of the teaser transformer are connected to an intermediate tap on the main transformers. A closed system is thus obtained when arcs are struck between the four upper electrodes and the bath of metal.

This system gives equal voltages in the arcs and therefore equal heating zones. When the electrodes are regulated for equal currents equal currents are taken from the three primary mains. The average power factor of the system on a non-inductive load is unity. Further advantages of the system are that when the furnace is under poor regulation the primary current remains tolerably balanced with a high power factor.

First, Second, Third Call—Liberty

MILL REFUSE AND POWDERED COAL FOR POWER GENERATION

Comparative Values of Coal, Oil and Mill Refuse, with Estimates of the Cost of Using Mill Refuse and Powdered Coal

"If the war continues it will probably be only a matter of time before fuel oil will not be available for power purposes where other fuel may be substituted," wrote J. D. Ross, superintendent of lighting of the Seattle Municipal Company recently. "The federal Fuel Administration is already inquiring into the possibilities of a change in fuel for our steam plant. A supply of coal suitable for use on stokers does not appear to be available at a price that can be considered for power purposes. The fuel problem, therefore, narrows down to the use of powdered coal, which makes it possible to use lower-grade coals. Mill refuse is at present largely an economic waste, and its use would therefore be considered as especially serving the national cause at this time."

Several alternatives present themselves: (1) To buy powdered coal; (2) to buy screenings and have the city pulverize them; (3) to buy mill refuse. Since the engineering problems in any case can be solved, the best procedure is determined largely by the cost of fuel delivered to the furnaces. This makes each fuel directly comparable with oil as now used.

Based on efficiencies obtainable in commercial practice (70 per cent) under fair average load condition, the following comparison of heating values can be made for the different fuel mentioned:

Fuel	Heat Convertible into Steam (B.t.u.)
1 unit of mill refuse.....	8,730,000
1 bbl. oil.....	4,351,200
1 ton coal (10,500 B.t.u.).....	14,700,000
1 ton coal (12,000 B.t.u.).....	18,800,000

Therefore the equivalent prices delivered to the fur-

naces will be in the following ratios: 1 bbl. oil : 1 unit mill refuse : 1 ton coal (10,500) : 1 ton coal (12,000) as 1 : 2 : 3.36 : 3.86.

Based on the above commercial efficiencies and allowing 20 lb. (9 kg.) of steam per kilowatt-hour, the following comparison can be made:

Fuel	Electrical Equivalent (Kw.hr.)
1 bbl. oil	225
1 unit mill refuse.....	450
1 ton powdered coal (10,500).....	756
1 ton powdered coal (12,000).....	870

The overhead charges on the equipment necessary for the use of various fuel have a marked influence on the economy of any fuel, especially when used for an auxiliary or standby plant. Their effect is less marked when the fuel is used for a strictly generating plant. The low overhead for oil equipment makes this fuel very desirable for an auxiliary plant, but the high prices now prevailing make it prohibitive for generating purposes. The high overhead for powdered coal equipment makes this fuel unsuited for small plants or for large plants having a small station factor. The comparatively lower investment for mill refuse than for powdered coal operates in favor of mill refuse for the lower loads, provided always that there is an ample, dependable supply of fuel.

COST OF USING MILL REFUSE

Estimate of extra equipment necessary when using mill refuse*:

Barges (eight), at \$6,000	\$48,000
Receiving dock	20,000
Conveying machinery	5,000
Storage bins, chutes, etc., in building.....	10,000
Remodeling eight furnaces	25,000
Incidentals	12,000

Total\$120,000

Estimated total cost per unit of fuel\$1.89
Fuel cost per kilowatt-hour (\$1.89 ÷ 450)..... 0.0042

COST OF USING POWDERED COAL

Estimated cost of powdered-coal equipment for 20,000-kw. plant\$200,000

Estimated cost per ton of passing coal through pulverizing plant, based on interest at 6 per cent, writing off investment in ten years and different continuous load:

Kw.		Kw.	
20,000	\$0.40	7,500	\$0.87
17,500	0.445	6,000	1.06
15,000	0.50	5,000	1.25
12,500	0.63	4,000	1.50
10,000	0.69	3,000	2.00

In the Seattle steam plant the output for 1917 was 12,000,000 kw.-hr., while in 1918 it was 24,000,000 kw.-hr. This output represents less than 3000 kw. continuous load; hence the cost for pulverizing would run high. For such a load 110,000 bbl. oil, 32,800 tons of coal (10,000 B.t.u.) or 55,000 units of mill refuse (8,730,000 effective B.t.u.) would be required.

In view of the present fuel situation and as a result of the analysis he has made of the economy of different fuels, Mr. Ross has recommended that bids be called to determine the price of the following in amounts of 45,000 and 75,000 units per year: Mill refuse f.o.b. mill and steam plant; screenings f.o.b. steam plant and mine.

*Includes f.o.b. mill, towing round trip, interest at 6 per cent, depreciation (writing off investment three and a half years), extra labor above oil (\$6,000).

LEAKAGE CURRENT CAUSED PITTING OF BEARINGS

Trouble Is Remedied by Attaching Brush to Bearing
at End of Shaft to Provide Short Path
to Ground

Owing to the presence of grounds and also because of weak insulation of some of the armature coils electrical leakage occurred on some of the motor-generators used in a generating plant serving a railway system. The leakage current transversed a path along the shaft

BRUSH FOR COLLECTING LEAKAGE CURRENT FROM
GENERATING SHAFT

and through the bearings, causing pitting or disintegration of the journal surfaces. As a remedy there was assembled and affixed to the end bearing a $\frac{3}{4}$ -in. by $1\frac{1}{4}$ -in. (19-mm. by 31.7-mm.) copper brush which afforded a low-resistance connection between the shaft and ground. It was made adjustable so as to provide for wear. After three years of use no pitting has developed.

Principal Safe, Interest Sure

INSTALLING APPARATUS TO PROTECT DAM FROM HEAVY ICE

Utilization of a 5-Hp. Air Compressor Prevents Ice
Formation During Winter Months, Releasing
Five or Six Men for Other Work

Some hydroelectric companies operating in a cold climate have found it advisable to cut ice away from spillways and Tainter gates during the winter because the expansion and contraction of the ice causes dangerous pressures on the dams. Others believe that the condition brought about by the rise and fall of the water level causes more danger.

One company with several dams in the Northwest looks upon the cost of keeping its spillways clear of ice as an investment to insure against breakdown. Ordinarily it requires the work of six or seven men to keep a 2-ft. (0.6-m.) space clear along one of this company's 750-ft. (228-m.) spillways. It is difficult to obtain men to do this work in severe weather, however, owing to the exposure they must undergo. To obviate this difficulty the company last winter rigged up an "agitating" apparatus to prevent the water freezing so quickly. The apparatus consisted of a 5-hp. motor driving an air compressor delivering air to a pipe laid about 2 ft. (9.6 m.) under the water, parallel to and just back of the spillway. At intervals of 18 in. (45

cm.) this pipe was punctured with needle holes through which the compressed air escaped into the water. The pipe was supported by brackets placed on the spillway and on the ice that was left intact. After the ice had once been cut clear of the spillway so as to permit this pipe to be installed it was easier to maintain the 2 ft. (0.6 m.) of open water. One man and the 5-hp. motor were all that was necessary under ordinary weather conditions. When the thermometer registered exceptionally low additional men were added to the force. The scheme resulted in minimizing the expense and remedied the labor problem.

Make the Total Large—Lend Now

MOUNTING THAT MAKES ARRESTERS CONVENIENT

Support of Protective Apparatus on Steel Structure
Attached to Building Wall Proves
Excellent Method

Because of lack of space inside one of its 12,000/2300-volt substations the Sanitary District of Chicago employed the arrangement illustrated herewith to support its protective apparatus and the incoming lines. This construction was considered preferable to some other alternatives because more steel would have been required if a roof structure had been employed, while at least two poles would have been necessary if a separate outdoor structure had been erected. This location of the apparatus is also attractive because it is accessible from a roof just below and still does not present a hazard to life.

The apparatus consists of Schweitzer-Conrad high-

PROTECTIVE APPARATUS READILY ACCESSIBLE FROM ROOF
BELOW

speed sphere-gap graded-resistance lightning arresters protecting three 12,000-volt, three-phase circuits. Each phase is equipped with a disconnecting switch and limit fuse, and the disconnecting switches are so connected that the arresters can be readily isolated for inspection and adjustment.

CENTRAL STATION SERVICE

Topics, Including Applications of Electric
Light, Power and Heat

USING CAMOUFLAGE IN HOUSE-WIRING CAMPAIGN

Company Advertises House-Wiring with Expectation of Accomplishing Many Things in Addition to Securing New Residential Contracts

A large central-station company in the Middle West is busily engaged in conducting a strong house-wiring advertising campaign. "How do you figure you can afford to make a bid for residential business now?" the sales manager was asked. He replied: "We have a great many prospective customers that we could reach by simply running a service. That would cost us only about \$6 per customer on the average, and we can afford to take on that class of business. The business of that sort which we will get will be the direct result of our campaign of advertising and intensive solicitation. In addition we will receive some indirect benefits. In the first place, there are about 4000 houses in this city that are wired but not connected. Some of them can be 'hooked up' in a campaign of this kind. Besides this, the curtailment of lighting in signs, street lighting, in windows and in houses has cut down the company's annual revenue at a rate that would amount to \$150,000 a year. If the company comes out as it now is and asks for new customers, the public and the municipality will soon begin to appreciate that the patriotic necessity for curtailment is apparently not so great as they imagined. So the house-wiring campaign may bring back to normal consumption some of the company's good sign and window lighting customers. Since the business of this class is largely the company's net, it is important that it be enticed back to normal as soon as possible."

Liberty Is in Peril—Will You Lend?

FINANCING NEW TIE LINES DESPITE WAR-TIME DEMANDS

Method That Is Meeting with Approval of Both Small and Large Companies in the Northwest When Coal Costs Are High

Under present conditions, with coal at a high level of prices and with winter-time deliveries of fuel very uncertain, many a company operating a small steam plant naturally feels that it would like to tie in with a neighboring large transmission company if possible. By so doing it not only shifts the generating responsibility to another company which may have some water power, but it also may reduce somewhat its production cost and put off into the far future any possibility of expenditures for plant replacements. From the small plant's viewpoint interconnection at the present time has many advantages.

When the tentative proposal to the transmission company is made, however, the difficulty of financing the

tie line between the present transmission system and the small steam plant looms large. The large company is having trouble taking care of the financing of necessary war business and its own community. The transmission company would be glad to furnish the service at 2.5 cents to 3 cents per kilowatt-hour, however, if the financial difficulty were not in the way.

In the Northwest a number of companies are getting around their troubles in a common-sense sort of way. The small company with the steam plant is financing the line and in turn is selling it to the transmission company, taking in payment the stock of the transmission company. This plan works well for several reasons. First, the small company can easily raise the money for the line in its own little community because its present security holders and the other investors in its town are in businesses that are not greatly affected by war. They are accustomed to putting their income in banks or putting it back into their local business and are willing to divert it to a local utility enterprise at a fair price. So the small company can raise the money. Second, it appears a good stroke of business to take the large company's stock in payment for the line because they get it at a price to yield around 8 per cent and are likely to come out handsomely or any advance in market value. This method is satisfactory to the large company particularly because it relieves it from the financial strain. It is usual practice for the small company to draw the specifications for the line it expects to build and then submit them to the engineers of the larger company for such revision as may be thought necessary to make them conform fairly well with the transmission company's standards of construction. The small company then does the actual building of the line. This has been found wise under present circumstances, for the small company can usually build the line at a great deal lower cost than the transmission company. At first it may seem paradoxical that the small company with less experience can build cheaper than a large concern with transmission specialists. It is true nevertheless. The difference in cost comes largely in the labor-camp and transportation expense. The small company can pick up labor in its own easy market and usually makes no special provision for housing and feeding the men. They know the community and shift for themselves. Farmers with teams do the hauling during lulls in farm work, and this keeps down transportation expense.

This plan of providing service has, therefore, many advantages to both companies. It is being used to the mutual advantage of concerns in the Middle West and Northwest and is at the same time making for increased capacity in the small towns and for conservation of the nation's fuel.

Our Boys Go—Shall Money Fail?

A DEPARTMENT TO LOOK AFTER THE TAX EXPENSE

Well-Organized Bureau Devoted to This Work Saves
Central-Station Company Considerable Money
by Its Endeavors

A Middle Western central-station company which has a department to look after all questions of taxation has found that this method of operation assists in preventing local taxing bodies from discriminating against it unjustly. This company's real estate and personal property taxes in recent years have increased from \$220,000 to \$240,000, but the ratio of its taxes to gross earnings decreased in the same period from 4.2 per cent to 3.9 per cent, relatively 7.1 per cent. The tax department of the company feels that this is a good record in view of the ratio of taxes to gross earnings shown by other companies in similar operating circumstances in the United States.

In making recommendations for continued activities of his department the taxation authority of this company recently said it did not appear reasonable to expect a decrease in valuation on the company's property in view of the rapid growth it was enjoying. He expressed the thought that the best policy would be to

maintain cordial relations with all local taxing authorities and to try to keep valuations at their present level. He suggested that one way to effect a reduction in the amount of taxes paid would be to reduce the number of subsidiary companies and thus to eliminate the duplicate payment of tax under the federal law on income passing from one company to another.

DATA ON THE OPERATION OF ELECTRIC FURNACES

Electrical and Tonnage Ratings of Various Sizes of
the Resistance Type—Some Types Pay for
Themselves Quickly

Thaddeus Bailey, president of the Electric Furnace Company, in a paper presented before the Chicago Section, American Institute of Electrical Engineers, gave data on electric furnaces of the resistance type which should be of value to commercial men of central stations in discussing this class of business with industrial plant "prospects." The field of the resistance-type furnace is mainly in operations requiring temperature between 400 deg. and 1650 deg. Fahr. (200 deg. and 900 deg. C.) and includes such work as annealing and heat treatment of steel and other metals and melting of non-ferrous metals, especially those with a strong affinity for oxygen.

One furnace with a 20-in. by 12-ft. (50.8 cm. by 3.7 m.) hearth used for annealing brass and silverware blanks handles 1 ton (0.9 t.) of blanks per hour with an energy input of about 200 kw. A motor-driven pusher mechanism pushes a pair carrying the blanks into the furnaces and discharges another pair on the other side into a quenching bath at the end of each annealing period. Another furnace of the same general type, but with its pusher mechanism automatically controlled by clock-actuated relays, is handling steel motor-car parts. Its hearth is 26 in. (66 cm.) wide by 12.5 ft. (3.8 m.) long. It is heating 800 lb. (282 kg.) of steel to 1650 deg. Fahr. per hour with an electrical input of 130 kw. A third size of this general type has a hearth 4 ft. (1.2 m.) wide by 20 ft. (6.1 m.) long. It is heating 1.5 tons (1.4 t.) of steel to 1650 deg. Fahr. per hour with an electrical rating of 360 kw. The largest size of this type in operation has a hearth 7 ft. (2.1 m.) wide and 20 ft. (6.1 m.) long and handles 3 tons (2.7 t.) of steel to 1650 deg. Fahr. per hour. It is rated at 660 kw. Equipments of this character, when automatically controlled by a contact-making pyrometer, reduce the human element to a minimum and lessen the chance for error in treatment. One man loads the pans. Drawbar knuckles and motor-car parts are among the products now being treated in these furnaces.

Another and somewhat similar type of furnace is known as the car type. With this type parts loaded on cars are pushed into the furnaces, treated and pushed out. Cast-steel parts for motor-car construction, locomotives and car axles, aluminum, copper, brass and gun castings and forgings are treated in these car-type furnaces. Among the sizes of this type now in operation are those with hearths 4 ft. (1.2 m.) wide and 10 ft. (3 m.) long, with a capacity of 0.5 tons (0.45 t.) per hour and a rating of 150 kw., and those larger sizes with 6-ft. (1.8-m.) by 18-ft. (5.5-m.) hearths

with a capacity of 1 ton (0.9 t.) of steel per hour and a rating of 300 kw.

A new type of furnace that is just being put into operation for annealing steel and copper is the recuperative car type. It is arranged to accommodate two lines of cars passing through the furnace in opposite directions, so that the hot outgoing cars give up some of their heat to the cold cars on the way in. This furnace, which is 22 ft. (6.7 m.) wide and 19 ft. (5.8 m.) long, is rated at 600 kw. It will heat 150 tons (143 t.) of steel to 1500 deg. Fahr. or 350 tons (317 t.) of copper or brass to 1200 deg. Fahr. (649 deg. C.) in twenty-four hours. No covers are required to keep the metal from scaling.

Another new type of special furnace is one built for reduction of tungsten ores. It is also of the car type. The cars with their contents are, however, moved continuously through the heated furnace, which is gas-tight. After being fully heated the cars are pushed into a long discharge hood to cool slowly. The furnace is built in one size only. It is 10 ft. (3 m.) wide, 50 ft. (15.2 m.) long, and has a capacity equivalent to annealing 0.5 ton (0.45 t.) of steel to 1650 deg. Fahr. (900 deg. C.) in one hour. It is rated at 150 kw.

Melting furnaces of the resistance type were also discussed by Mr. Bailey as apparatus for melting brass, copper, zinc and aluminum. Tilting furnaces for this work with a hearth capacity of 1500 lb. (680 kg.) and a melting rate of 600 lb. (272 kg.) per hour are rated at 105 kw. The metal losses on furnaces of this type when handling yellow brass and pouring at 2200 deg. Fahr. are always less than 1.5 per cent. They are used in making extrusion press billets, castings for plumbers' supplies and slabs for cartridge case rolling. Operating records of these furnaces in actual use show that in melting brass the energy consumption averages one weekly runs from 540 kw.-hr. per ton to 515 kw.-hr. per ton. Non-tilting furnaces of the same general type

These furnaces, Mr. Bailey stated, impart no particular quality to the metal treated because of their electric operation, but they are tools that for particular heating operations more closely approach the ideal equipment than any others in commercial use. In some cases these furnaces effect considerable saving over other methods. This is especially true where automatic heat treatment permits reduced labor cost and reduces the quantity of rejected products. In melting brass large savings are shown over crucible or open-flame furnaces, as electric furnaces permitting control of the furnace atmosphere reduce the zinc losses from 3 per cent to 4 per cent over the open-flame type and 2 per cent over the crucible type. Moreover, eliminating the crucible cost strikes out such a great item of expense that an electric furnace will often pay for itself in three or four months, where it replaces a crucible furnace even with energy at 2 cents a kilowatt-hour.

Will You Lend for Human Freedom?

USING BILL FORM WITH TWO DETACHABLE SLIPS

One for Cashier's Memorandum and the Other for the Collector—Latter Slip Is Used When Customer Mislays Bill

The Lehigh Valley Light & Power Company, Allentown, Pa., uses a bill form with two slips as illustrated, one a cashier's memorandum and the other a collector's memorandum. The latter is filled out at the same time the bills are made out in the billing department, all of which is done at one point. These collectors' slips are then detached from the bills before delivery and sent to the local offices where they are due. In this way a customer wishing to pay his bill but failing to bring the statement with him can very quickly be informed of the

with a hearth capacity of 7000 lb. (3175 kg.) of aluminum and a melting rate of 2000 lb. (907 kg.) of aluminum per hour are rated at 500 kw. The hearth measures 4 ft. (1.2 m.) wide and 10 ft. (3 m.) long. This same furnace used on brass or copper has a hearth capacity of 12,000 lb. (5443 kg.) and a melting rate of 000 lb. (1814 kg.) of brass per hour.

amount due. His payment can be accepted without telephoning or reference to other departments.

Immediately after the discount period these slips are returned to the bookkeeping department, where by removing those paid from the list there is left a complete record of delinquent customers, which is immediately turned over to the collector.

TECHNICAL THEORY & PRACTICE

Including a Digest of Important Articles Appearing in
the Scientific and Engineering Press
of the World

Generators, Motors and Transformers

Magnetic Pull on Armatures of Electrical Machines.—E. ROSENBERG.—The maximum value of the one-sided pull is given by $F = C\pi DL(B/5000)^2(x/a_1)$, where πDL is the cylindrical surface of the armature and C has a value nearly equal to $2/3$ except for two-pole machines with salient poles, in which cases C is about 0.4 . B is the flux density at the point on the saturation curve for which the inclination of the curve is about five-sixths of that of the straight part of the curve.—*Science Abstracts, Section B*, Jan. 31, 1918 (abstracted from *Elektrotechnik und Maschinenbau*, Nov. 4 and 11, 1917).

Automatic Starting of Motors of Medium Rating.—PIERRE LEGRAND.—For direct-current motors, automatic starting is a relatively simple problem, solved by the use of either contactors or auxiliary starting motors. The principles underlying both these types of methods are described and their requirements outlined. With alternating-current motors it is necessary to have the contactor coils in circuit with the primary current of the stator and also to delay the action of the mechanism by a dash-pot, a method which, however, becomes ineffective with motors of 100 hp. and more. Compromises have been made by the use of an auxiliary dynamo. Some engineers prefer the auxiliary starting motor. These methods are also described by the author, who in conclusion dwells upon the large economy that can be realized by the employment of automatic starters.—*L'Industrie Electrique*, Jan. 25, 1918.

Generation, Transmission and Distribution

Transformer Losses in Large Rural Distribution Systems.—H. ROTH.—Two systems are compared. In the first the energy is transmitted and distributed at 20,000 volts or 30,000 volts. In the second the energy is transmitted to transformer stations at 30,000 volts to 50,000 volts and distributed at a lower pressure, say 6000 volts. Allowing for the extra copper losses in the intermediate transformers totaling 6000 kva., it is shown that when the distribution voltage is 20,000 the intermediate transformers increase the losses by about 20 per cent, but when the distribution pressure is only 6000 volts the losses are decreased by 4 per cent.—*Science Abstracts, Section B*, Jan. 31, 1918 (abstracted from *Elektrotechnische Zeitschrift*, Oct. 18, 1917).

Transmission-Line Practice; Sag and Span Problems.—LIEUT. E. T. DRIVER and E. V. PANNELL.—The authors give the fundamental formulas for determining sag and span and then point out how temperature, wind, sleet, etc., affect different kinds of conductors, including copper, aluminum, aluminum-steel and copper-clad steel. Tables and curves are given for calculating the sag on copper conductors when the ice and wind loading is relieved, increase in sag from 0 deg. to 120 deg. Fahr. with 600-ft. (182.8-m.) copper cables, and

sag in feet and stress in pounds per square inch for different classes of cable on a 600-ft. span.—*Toronto Electrical News*, Feb. 1, 1918.

Electric Power Supply in Great Britain.—LEON GASTER.—In this article the author comments on the report recently issued by the coal conservation sub-committee of the reconstruction committee. In part he says that small generating stations are admittedly uneconomical. It is estimated that the adoption of the scheme recommended by the committee will result in an annual saving of about 57,000,000 tons of coal. This scheme is also commendable as it will increase the industrial output for a given coal consumption. The great advantage to the lamp industry of a standard voltage should also be borne in mind. In selecting the sites for the generating stations and in the choice of plant the possibility of working hand in hand with the gas supply companies should be carefully considered, as in this way the by-products of the coal can be utilized before it is used in the generation of electricity.—*London Illuminating Engineer*, December, 1917.

Ground Connections for Distribution Systems.—W. C. HESTON.—The great cost of ordinary grounding methods for overhead distributing systems has led a Portland company to experiment with various types of ground to see whether a more inexpensive method might not be found which would meet requirements. The results of these comprehensive tests and the conclusions drawn from them are presented in this article.—*Journal of Electricity*, March 1, 1918.

Control of Large Amounts of Power.—W. B. WETMORE.—The author considers in detail where reactance should be inserted so as to limit and confine disturbances on large networks. The subjects of limitation of disturbances, generator reactance, feeder reactance, voltage disturbance, busbar reactance, transfer of power, parallel operation and the limiting effect of fault resistance were also discussed.—*London Electrician*, March 8, 1918.

Installations, Systems and Appliances

Electric Purification of Gas.—J. SAGET.—A historic summary of the various processes used to eliminate solid or liquid particles contained in gas. Electrical apparatus which causes the ionization of these particles and expels them from the electric field created is described.—*Revue Générale de l'Electricité*, Feb. 9, 1918.

Constant-Torque Magnetic Clutch.—The action of a new magnetic clutch used in driving a dynamo for electric welding is explained. The clutch consists essentially of a differential electromagnetic coupling, which will release on overloads. The article is illustrated with diagrams of connections, construction details, efficiency curves, etc.—*London Electrician*, Jan. 25, 1918.

Labor-Aiding Appliances in Steel Works.—S. WELL-MAN.—The subject of handling pig iron and scrap by the open-hearth charging machines and lifting magnets is discussed, it being stated that the saving in labor charges in American steel works by the use of these appliances amounts to nearly \$100,000,000 per annum. Every open-hearth plant of any size in the world to-day is equipped with these auxiliaries, says the author, and they are considered as much a necessary part of the equipment as the furnace itself.—*London Electrician*, March 8, 1918.

High-Temperature Processes and Products.—Electric furnaces are now being used by the thousands for the purpose of hardening dies and gages. In some instances these furnaces are also used for gear hardening. Another important product of the electric furnace is carborundum. There are more than seventy electrical furnaces in Sheffield, England, for refining steel, having an output of over 150,000 tons per annum.—*London Electrician*, March 1, 1918.

Electroculture at Chester, England.—An interesting report on electroculture experiments carried out during the summer has just been presented by S. E. Britton. The electrical equipment consisted of a 10-in. (25.4-cm.) induction coil with mercury-break current interrupter, Lodge valves and an earth plate. An elevated net of No. 30 galvanized-steel wires placed 15 ft. (4.57 m.) apart and hooked to 7/16-in. (1.6-cm.) span wires by insulators, was used for the one electrode, the whole being supported by six poles. To each of the poles was fixed a wrought-iron bar which enabled the discharge wires to be placed at any distance above the ground between 2 ft. 6 in. (76.2 cm.) and 6 ft. 6 in. (198.1 cm.). The apparatus was supplied with 5 amp. at 210 volts direct current to maintain a spark $\frac{3}{4}$ in. (1.9 cm.) long when an earth wire was placed that distance from any part of the discharge network. At the beginning the discharge wire was placed as near as possible to the ground, and, as the crop grew, raised to about 6 in. (15.2 cm.) above the foliage. This experiment indicated that it is not detrimental to place the discharge wire near to the plants, and it was concluded that electroculture increased potato crops as much as 153 per cent in some cases. Some kinds of potatoes thrived better than others under this treatment.—*Toronto Electrical News*, March 15, 1918.

Electrophysics and Magnetism

Magnetization of Iron in the Absence of Hysteresis.—WINTHROP R. WRIGHT.—In general two methods have been proposed for suppressing hysteresis, namely, mechanical shocks or vibrations and an alternating magnetic field, either transverse or longitudinal. While Ewing employed mechanical vibration, others used alternating-current fields superposed upon the magnetic field and yet others investigated the change of magnetization with the temperature. A table giving the composition of steels in per cent is included in the article.—*Physical Review*, March, 1918.

Electrochemistry and Batteries

Stellite as a Substitute for Platinum.—E. HAYNES.—Refers to the present scarcity of platinum and to possible substitutes. An alloy of gold and palladium is probably the best alternative material. While the cost is high, bulk for bulk, it is only half that of plat-

inum. The alloys of nickel with chromium, silicon with iron and pure quartz have also given satisfactory results where resistance to acid attack is the requirement.—*Proceedings of the American Chemical Society*.

Units, Measurements and Instruments

Three Devices for Use in Electrometry.—E. H. KENNARD.—A method is suggested for increasing the deflections of an electrometer under circumstances where the scale cannot be conveniently placed a long distance from the mirror. The suggestion is that a concave lens be interposed between the mirror and scale to magnify the deflection. Sometimes a simple means of connecting two wires together is desired which will permit of easier disconnection than a soldered joint and yet will not introduce the additional capacity and possible leakage of a key. For this purpose a little silver cup may be soldered to one wire and the other wire attached to a piece of heavy wire tipped with a silver point and bent so that the point rests upon the floor of the cup. To obtain time signals at rather long intervals, a torsion pendulum is more useful than a gravity pendulum because of the ease with which the period may be varied over a wide range.—*Science*, March 15, 1918.

An Electrical Instrument for Recording Sea-Water Salinity.—ERNEST E. WEIBEL and ALBERT L. THURAS.—An apparatus to give a continued record of sea-water salinity by the measurement of its electrical conductivity is described. A pair of electrolytic cells has been designed which when used with a suitable alternating-current galvanometer will give satisfactory operation in connection with a recorder. The temperature compensation is obtained by immersing both cells connected in the two arms of a Wheatstone bridge in a bath of uniform temperature.—*Journal of the Washington Academy of Sciences*, March 19, 1918.

Power Plant Instruments as an Investment.—M. A. SALLER.—This article deals with the installation of automatic feed-water regulators, the author saying that they should be an excellent investment in practically every plant, except possibly in small plants running at a very steady load, where the feed pumps can be run at a steady rate just sufficient to supply the feed water as fast as it is being evaporated. Among the benefits which can be derived from their use are the following: (1) Elimination of the uncertainty attendant on hand regulation; (2) firemen or boiler-room force relieved of this care and attention; (3) provision of a continuous feed in accordance with load demands, making possible the maintenance of the highest attainable feed temperature; (4) maintenance of a steady water level which results in the production of drier steam; (5) improved firing and furnace conditions, and (6) reduction in wear and tear by eliminating expansion and contraction strains in the boiler. Wherever a variable or fluctuating load is encountered the automatic regulator can be arranged to adjust the feeding of the water to the particular load conditions.—*Power Plant Engineering*, Chicago, March 15, 1918.

Temperature Effects in Direct-Current Meters.—G. W. STUBBINGS.—The author points out that a temperature variation of 3 deg. C. will cause a variation in the accuracy of an unshunted mercury meter of about 1 per cent. When two such meters are being used, one at

20 deg. C. and the other at 8 deg. C., there will be 4 per cent difference in the accuracy of the two meters. Then follows a discussion of the magnitude of the temperature coefficient of various types of meters. In meters like the shunted watt-hour type the elimination of temperature effect should be more feasible than in the simpler types, owing to the greater number of available adjustments. The high temperature coefficient is a serious defect in the small mercury meter. There seems no simple way in which it can be decreased, and until the problem is solved the commutator meter will retain an advantage over the small mercury meter in that the temperature coefficient of the former meter can be made as small as may be desired.—*London Electrical Review*, March 1, 1918.

Telegraphy, Telephony and Signals

Stray Interference in Radio-Telephony.—ALFRED N. GOLDSMITH.—With the more sensitive receivers—*e. g.*, the regenerative vacuum tube receivers—heavy "strays" have a more detrimental effect than merely to cause noises. They break up the incoming sustained wave trains of the receiving system and thus prevent the utilization of resonance phenomena in circuits having small damping ability. Some types of detectors—*e. g.*, the sensitive crystals or gas-containing bulbs—may be paralyzed by heavy strays and require some time to regain their sensitiveness. Even very high-vacuum tubes may show this effect, since a powerful stray impulse may charge the grid negatively to such an extent that the plate current will be practically cut off until the grid charge escapes by the normal leakage. In some tests over considerable distances it was found that good reception requires that the signal audibility shall be three times that of the strays and that the strays shall not occur continuously even then, but intermittently and not more frequently than say once or twice per second. Reception becomes difficult if the strays are five times as strong as the signal, and almost impossible if the ratio is greater, particularly if the strays are continuous. The effective range of a radiophone transmitter depends on the loudness of strays at the receiving station, and consequently any method of reducing strays should increase the effective power of the transmitter in just that proportion.—*Wireless Age*, March, 1918.

Wartime Wireless Instruction.—E. E. BUCHER.—Ninth article of a practical course for radio operators. Among the subjects covered are coupled transmitter circuits in radiotelegraphy, wave length and frequency.—*Wireless Age*, January, 1918.

Signal Officers' Training Course.—MAJOR-J. ANDREW WHITE.—Eight articles in a series intended for instructing soldiers preparing for United States Army service. This article deals with the radio apparatus of the Signal Corps and describes the construction and operation of the equipment used. Among the subjects covered are the following: Sectional mast, antenna and counterpoise, generator, speed indicator, gearing, connections, operating chest, quenched-spark gap and tuning of sending set and receiving set. Some useful data are given in the accompanying tables.—*Wireless Age*, January, 1918.

Receiver for Undamped Oscillations.—By means of a combination of capacity and shunt resistance, it is possible to adjust the voltage of a plate battery to a

value higher than would be possible without its use. A critical adjustment of the value is thus obtained, so that the effect of very minute disturbances impressed thereon causes a much greater flow of current through head telephones when receiving damped and undamped oscillations.—*Wireless Age*, March, 1918.

Figuring for the Power Plant.—P. A. PRICE.—The article gives data required for the determination of power plants for common-battery telephone exchanges and shows how these data are applied to practical cases to provide for future exchange growth.—*Telephony*, March 16, 1918.

Miscellaneous

Hydroelectric Power and University Instruction.—With the development of hydroelectric power in the Alpine and other regions of France, certain industries—*e. g.*, electrochemical, electrometallurgical, general mechanical engineering, paper-making, etc.—are also being developed. The Polytechnic Institute attached to the university intends to keep pace with the requirements that will grow for technically trained men for the electrical and allied industries. In an article in *La Nature* for Feb. 9 the director of the Polytechnic outlines the courses of instruction held at the institute. The establishment comprises (1) a high school of electrotechnics for training electrical engineers, electrochemists, electrometallurgists, etc.; (2) an elementary electrotechnical school; (3) an electrical standardizing and testing laboratory; (4) a school for the paper-making industry; (5) a paper-testing laboratory; (6) an electrochemical and electrometallurgical test station with a 1000-hp. experimental plant. A chair of electrochemistry and electrometallurgy has also been established at the university.—*London Electrical Review*, March 1, 1918.

The Fertilizer Industry and Its Power Requirements.—J. E. MELLETT.—The power requirements of different types of plants are given, the different operations discussed, and the kilowatt-hour consumption and power cost per unit of product are presented for several plants engaged in this work.—*General Electric Review*, February, 1918.

Constant Heat for Metal Electrode Welding.—ROBERT E. KINKEAD.—Believing that constant-arc temperature requires constant current, many persons believe that the latter condition is essential for welding. On the other hand, constant heat in an arc requires that the product of the current and voltage be constant. The author expresses the opinion that designers of electric welding apparatus have neglected the technical details that should have influenced them.—*Railway Electrical Engineer*, March, 1918.

Revision of Boiler Code.—The revisions of the boiler code made recently by the American Society of Mechanical Engineers are outlined.—*Journal of the American Society of Mechanical Engineers*, March, 1918.

Purchasing Coal by Specification and Methods of Sampling.—J. A. MOYER and J. P. CALDERWOOD.—This article, embodying information of considerable value, deals with the purchasing, specifying, sampling and analysis of coal, the calorific value requirements, and methods of its determination. The specifications issued by several companies, corporations and engineering societies are quoted.—*Pennsylvania State College Engineering Experimental Station Report*, 1916.

NEWS OF THE INDUSTRY

Chronicle of Important Events and General Activities
in the Technical, Commercial and
Manufacturing Fields

MEMBERS OF A. I. E. E. IN UNIFORMED WAR-SERVICE

Total Number Up to April 1 Was 760, or More than
8 per Cent of the Aggregate Membership,
Which Is 9200

F. L. Hutchinson, secretary American Institute of Electrical Engineers, states that the total number of members in the uniformed service, including those instances of which notice was received after the Year Book went to press and up to April 1, is 760. This is more than 8 per cent of the total membership, now in excess of 9200.

In the 1918 Institute Year Book the names of members who are in the army or navy of the United States or of an allied nation have been designated by a special entry in every case where notification to this effect had reached the secretary.

ILLUMINATING ENGINEERS TO HOLD A CONVENTION

Society Council Approves Tentative Report of Committee on Time and Place—One-Day Technical Session on War Lighting

A tentative report has been made to the council of the Illuminating Engineering Society by the committee on time and place for the annual convention.

The members of this committee, on which are representatives of each section, decided that the usual annual convention, including the entertainment features and excursions, was undesirable at this time. The consensus of opinion favored a short technical session.

The council approved the report and decided that a one-day technical session consisting of papers on lighting subjects pertaining to the war should be held. Details as to time and place were left in the hands of the committee, which will make such further recommendations to the council as seem advisable in the light of future conditions.

N. E. L. A. CONVENTION TO BE AT ATLANTIC CITY

June 13 and 14 Have Been Fixed as the Time for Annual Meeting at the Famous New Jersey Seashore Resort

The convention committee of the National Electric Light Association decided unanimously on April 3 to recommend to the officers of the association to hold the annual meeting, devoted entirely to war problems, at Atlantic City on June 13 and 14, with the Hotel Traymore as headquarters. President Lieb has decided accordingly.

While it is felt that it is necessary under the constitution to hold the annual meeting, the essential requirement is the limitation of work in the meeting to the consideration of pressing and vital war problems as related to the industry. In view of the fact, however, that practically all member companies are short-handed and that their officers have their time taken up not only with general problems of the industry but with local problems and difficulties that come upon them as patriotic citizens, it is believed that the attendance at the meeting will inevitably be much smaller and more restricted than would occur in normal times and under the usual conditions, all other subjects, however important, being swallowed up for the time being in the fundamentally vital and essential one of winning the war.

The convention committee is composed of Walter Neumuller, New York, chairman; T. C. Martin, New York, secretary; H. C. Abell, New York; J. L. Bailey, Baltimore; R. H. Ballard, Los Angeles; M. R. Bump, New York; J. E. Davidson, Omaha; Leavitt Edgar,

Helping to Sell the Third Liberty Loan

Typical Example of the Part of Electrical Men Seen in Boston, Where a Great Parade Opened the Campaign—Central Station Employees and Others Swell the Totals

THROUGHOUT the country the different branches of the electrical industry are giving their earnest attention to the best ways and means of advertising and selling the third Liberty loan. Typical of their activities is the part taken in the great parade in Boston on Saturday, April 6.

Although it was 6.45 p. m. when the section of the Edison Electric Illuminating Company of Boston reached the reviewing stand it presented an imposing appearance. President C. L. Edgar marched at the head of his employees. Behind, in the first row, were General Superintendent W. H. Atkins and bureau chiefs; the Edison company service flag with 300 stars; the Edison girls' section; the Edison Red Cross float, with boat symbolizing carrying aid across the water to the front, and the men's contingent.

Edwin S. Webster led the Stone & Webster contingent in the same parade, and directly following him were Russell Robb and Henry G. Bradlee of the firm.

NEW ENGLAND CENTRAL STATIONS AND THE LIBERTY LOANS

Every central station in New England with which the ELECTRICAL WORLD has been in touch as the campaign for the third Liberty loan opens is in hearty sympathy with the raising of funds for the war work of the government. In general the companies do not purchase and carry the bonds for the employees, leaving that for the banks. The latter are usually so well organized to do this work that the central stations have not found it necessary or desirable to underwrite the loans on behalf of their own people, speaking generally.

The companies, however, are co-operating with the banks in every way and in many cases are deducting from salaries and wages, with the consent of employees, the installment payments required where the bonds are not purchased outright. In some cases companies purchase bonds on their own corporate accounts, but this is not a general practice in view of the present high cost of money.

Not many of the central stations in New England have issued publicity material of their own composition bearing upon the Liberty loans, but special plans for the sale of bonds have been carried out successfully, in addition to the routine banking methods. The central stations operated by C. D. Parker & Company of Boston, instead of making a Christmas gift of money to their employees last year, anticipated this in the cases of those purchasing fifty-dollar bonds on installments by crediting each purchaser at the beginning of the second loan drive in October with the first ten weekly payments, amounting to \$10 per bond. This plan encouraged subscriptions and was much appreciated throughout the organization.

Employees of the Edison Electric Illuminating Company of Boston took \$80,000 bonds on the first loan and \$78,000 on the second, subscriptions being made through a local savings bank. *Edison Life*, the com-

pany's monthly publication for employees, supported the loans most vigorously in both editorial and reading pages. The company has about 2000 employees, and the general plan of installment payments from wages and salaries was followed, usually one man from each department looking after the deposits at the bank. On its own account the company purchased bonds of the second loan to the amount of \$530,000. The treasurer of the company gave a number of talks to employees in groups on the earlier loans. The third loan is being handled through a committee headed by J. W. Cowles, superintendent of installations, and it is expected that the same general arrangement as in the first two will be followed.

The Narragansett Electric Lighting Company, Providence, R. I., purchased bonds and carried them for its employees in the first two loans and will do the same

FLOAT OF EDISON ELECTRIC ILLUMINATING COMPANY

this time. The usual \$1 per week payment basis per \$50 bond was required. The company gave its employees all coupons. About 200 employees purchased bonds in the first two loans, aggregating \$34,000. The employees of the Worcester (Mass.) Electric Light Company subscribed to bonds to the amount of \$14,300 on the first two loans, \$1 per week payments being made on the fifty-dollar basis. The company purchased bonds to the amount of \$154,800 in its own name, but did not carry its employees' bonds. About 90 per cent of the employees subscribed.

At Hartford, Conn., the industrial and public utility subscriptions to the Liberty loans were handled in large measure through the Aetna Life Insurance Company, which worked out a most successful plan under the personal supervision of its president, former Governor and United States Senator Morgan G. Bulkeley. The Hartford Electric Light Company participated in this plan, under which twenty months is allowed for payment on the bond, an unusually liberal period. On the first loan the Aetna company allowed 3.5 per cent interest on the money paid in by the subscriber; on the second loan 4 per cent, and the third loan will be handled along the same lines but with 4.25 per cent interest allowance.

Business Men in Great Chicago Meeting

Government Organization in Relation to Business in War, the Railroads, Financing of War and Ships the Supreme Questions Before United States Chamber of Commerce

FOUR questions of supreme importance to the nation as a whole and to the American business world formed the nucleus around which the sixth annual convention of the Chamber of Commerce of the United States, held this week in Chicago, centered. These were government organization in relation to business in war, the railroads, the financing of war and ships. The definite, practical and concrete things that business can do not only to assure the future of this country, a speedy victory and a solution of the labor problems but also to keep intact the germ of existing but less essential industries so that they may blossom forth with renewed vigor after the war were discussed from all angles. Business men of the highest rank, Cabinet officers, bankers and economists contributed greatly to the importance of the convention and its deliberations. As an evidence of the universality and recognition of general business in the war may be cited the addresses of Secretaries Daniels and Lane and that of Earl Reading, the British Ambassador. Business could ask no greater recognition than the presence of these men at its sessions.

R. Goodwyn Rhett, president of the chamber, painted the vision of America in glowing color, reminding his hearers of their greater obligations to civilization and to country than to themselves. That the great development of this country and of its resources has been due in large part to the energy, enterprise and genius of the American business man was the idea developed. His was the leadership, the vision and the courage to follow that vision to realization. Linking this idea up with his conception of the mission of the United States Chamber of Commerce, Mr. Rhett said: "To me the highest mission of this chamber is to put a soul into business, to transform the cold clay into the sentient being, to transfuse into the marble statue the warm blood of the human being that will make its face to shine, its eyes to glow, its hands to clasp, its heart to beat and its soul to vision. In that sentient being only can democracy find its safeguard and protection. When business men have found out that what is not good for the country is not good for business and have transmitted that creed to their fellow citizens and made them understand that it should also be the creed of liberty, of agriculture, of the citizenship of America, they will have placed democracy on a broader foundation and have mounted infinitely higher in the scale of civilization."

Reports of the various committees were presented at the Tuesday afternoon session and on Wednesday morning. On Wednesday afternoon the following reports were made: Finance, Charles S. Hamlin, Federal Reserve Board; railroads, Harry A. Wheeler, chairman National Chamber's committee on railroads. The chamber's activities in relation to government organization, shipping and finance were presented in brief addresses by Waddill Catchings, chairman war committee; Edward A. Filene, chairman war shipping com-

mittee, and Wallace D. Simmons, chairman committee on finance.

On Wednesday evening the Auditorium theater was filled to capacity—for the convention was the largest ever held by the chamber—to listen to addresses by Josephus Daniels, Secretary of the Navy, and Franklin K. Lane, Secretary of the Interior.

Secretary Daniels devoted the major portion of his speech to a recital of the achievements of the American navy in convoying troops to France and in patrolling the seas in conjunction with the fleets of the Allies. He accentuated the fact that ships are vitally necessary in winning the war and urged the business men of the country to give up skilled mechanics so that the ship-building program can be carried through without delay.

Secretary Lane, in the midst of a very patriotic speech, outlined a scheme for caring for the returning armies of the United States when the war is over. Secretary Lane said: "We must think of the making of a new America, and we must begin with the boys who come back from the front. I say that every one of these men should have an opportunity to acquire a piece of the soil of the United States. We have along the lines of the Colorado River a million acres which can be irrigated if we will dam that river and develop power and hoist that water on to the mesa. It will take vast numbers of men from the returning army to build these dams and put up that power plant. I would pay those boys in farms on the mesa itself: Let each man have his forty acres of irrigated land with a house, with stock, and let him pay Uncle Sam in labor for it by constructing the works which make it possible."

There were indications in Chicago during the convention that this proposal of Secretary Lane might come forward in the form of bills in Congress before long.

THURSDAY'S FOUR SESSIONS

Four sessions were held simultaneously on Thursday, one devoted to government organization in relation to business in war, the second devoted to finance, the third to railroads and highway transportation, and the fourth to shipping.

Waddill Catchings, chairman of the war service executive committee of the Chamber of Commerce, presided and addressed the meeting on the war-time organization of industry. The discussion that followed embraced these topics: (a) What principles should be adopted by the government as the basis of price control? (b) To what extent should the government fix prices? (c) What regulations should govern the determining of priorities? (d) What is a non-essential industry under war conditions? "How shall employer and employee co-operate to maintain war-time production?" was discussed by Prof. Leon C. Marshall of the University of Chicago, until recently secretary of the advisory committee of labor administration, Department of Labor. William H. Vandervort, a member of the official conference board of employers and employees,

also spoke. "Reconstruction in Foreign Trade" was the subject of an address by Dr. Frank W. Taussig, chairman United States Tariff Board. James G. White of New York City was another speaker.

Charles A. Hinsch, president American Bankers' Association, presided at the session on finance. "Trade Acceptances" were discussed by Lewis E. Pierson, chairman of the board of directors of the Irving National Bank, New York; George Woodruff, president First National Bank, Joliet, Ill.; W. B. Fish, treasurer Printz Biederman Company, Cleveland, Ohio; Wallace D. Simmons, president Simmons Hardware Company, and George H. Paine of Philadelphia. "The Effect of Government Financing on Industries" was dealt with by David R. Forgan, president National City Bank, Chicago; Thomas N. McCarter, president of the Public Service Corporation of New Jersey, Newark, N. J., an abstract of whose address is given below; August H. Vogel, secretary and treasurer Pfister & Vogel Leather Company, Milwaukee, Wis.; John V. Farwell, president John V. Farwell Company, Chicago, and O. M. W. Sprague, professor of economics at Harvard University. "How May Helping the Shipbuilders Best Be Made the Business of Local Organizations?" was the subject of addresses by Charles E. Falconer, chairman of the war shipping committee, Baltimore; Edgar S. McKaig, secretary of the war shipping committee, Philadelphia, and Crawford H. Ellis, chairman of the shipbuilding committee of the Louisiana State Council of Defense.

Harry A. Wheeler, chairman of the chamber's committee on railroads, presided at the transportation session. "Motive Power" was the subject of Alba B. Johnson, president Baldwin Locomotive Works; "Terminals," that of John F. Wallace, chairman Chicago Railway Terminal Commission; "Car Supply," Samuel O. Dunn, editor *Railway Age*; "Extensions," Francis H. Sisson, vice-president Guaranty Trust Company, New York. Roy D. Chapin, chairman highway transportation committee of the Council of National Defense; F. A. Seiberling, president Goodyear Tire & Rubber Company; A. C. Bedford, president Standard Oil Company of New Jersey and chairman of the petroleum war service committee, and M. H. G. Shirley, chief engineer State Roads Commission of Maryland, were other speakers.

Edward A. Filene, chairman of the war shipping committee of the Chamber of Commerce, presided at the session to consider shipping problems. "How Can We Get More Ships in the Next Six Months?" was discussed by Charles Piez, vice-president and general manager Emergency Fleet Corporation; "Patriotic Labor," by Dr. Charles A. Eaton, national service department, Emergency Fleet Corporation; "Big-Scale Shipbuilding," by Joseph W. Powell, vice-president Bethlehem Shipbuilding Corporation; "The Rochester Plan," by James T. Hutchings, general manager and vice-president Rochester Railway & Light Company; "Reducing Ship Labor Turnover," by Meyer Bloomfield, head of the industrial service department Emergency Fleet Corporation; "The World's Ship Labor," by Crawford Vaughan, ex-Premier of South Australia; "The Fabricated Ship and Its Part in the War," by George J. Baldwin, president American International Shipbuilding Corporation.

Following these specialized discussions there was a general conference on Thursday afternoon under the

chairmanship of B. D. Caldwell, war shipping committee, New York, dealing with the following topics: "Should Business Men Help the Transference of Their Skilled Employees to Shipyards?" B. F. McLeod, Charleston, S. C., and N. Sumner Myrick, vice-chairman National War Shipping Committee; "What Can the Local Business Organizations Do in Helping to Provide Adequate Transportation Facilities for Ship Workers?" Philip H. Gadsden, president Charleston Light & Power Company, Charleston, S. C.; "What Can the Local Organizations Do to Provide Adequate Housing Facilities for the Ship Worker for the Next Six Months and Thereafter?" J. R. Flannery, manager division of general service, Emergency Fleet Corporation, and Bert L. Fenner, head of production department, Department of Labor; "What Can Business Organizations Do to Express Their Appreciation of Ship Workers and Their Work as an Encouragement to Utmost Effort?" V. Everit Macy, chairman adjustment board, Department of Labor; "What Can the Local Business Organization Do to Make Two or Three Shifts in the Shipyards Possible?" Holden A. Evans, president Baltimore Dry Dock & Shipbuilding Company, and J. B. Weaver, manager Harlan plant, Bethlehem Shipbuilding Corporation.

The feature of Thursday's session was the address of the British Ambassador in the evening. Friday was given over to a war convention of secretaries. Throughout the entire convention there was manifest a spirit of determination to subordinate all business to the great business of winning the war and that quickly. Patriotic enthusiasm bubbled from every speaker and optimism was everywhere apparent.

ADDRESS OF MR. MCCARTER

Mr. McCarter showed in his address the vital importance of utilities to the country, saying in part:

If this country is ultimately to take its place in the forefront of the Allies and be the final decisive factor in the termination of the world war, as we all believe, the integrity of the utility industry of this country must not only be preserved but its activities must be speeded up to a point never hitherto attained; its capacity for service must be greatly increased, and the capital necessary to accomplish this result must be provided. The power companies must keep pace with the extraordinary demands being made upon them to furnish power in large quantities to the shipyards, to the aeroplane factories and to the innumerable industries engaged either exclusively in the manufacture of war products or of materials which ultimately become a part of them.

The utilities of the country constitute, if I may make use of the term, no "piker" industry. Viewed from every angle—from that of service rendered, from that of annual income, and from that of capitalization—they constitute a highly important factor in the economic life of the nation. They daily furnish the public with necessities of modern civilization. Their securities are owned by millions of people, as well as by financial institutions. It would be difficult to find a banking institution in the country that would not be embarrassed by a permanent collapse of the credit of these utilities. Like those of every other industry in the country, their costs over pre-war conditions have enormously increased. It is susceptible of proof that their labor and material costs have increased by an average of 70 per cent. Unlike the ordinary private industry, however, they have not been able to "pass the buck" of increased costs to the consumer.

There is now a country-wide movement under way by the utilities for increased revenue. In many cases, I am happy to say, the state commissions are facing the issue courageously and granting the necessary increases; but if widespread disaster is to be averted, a public spirit of fairness and justice to these companies must be developed that will quickly manifest itself in commission decisions.

Invest Safely—Buy Liberty Bonds

LABOR AND CAPITAL UNITED FOR THE WAR

BY LOYAL A. OSBORNE,

Vice President Westinghouse Electric & Manufacturing Company

[At the request of the ELECTRICAL WORLD Loyall A. Osborne, vice-president Westinghouse Electric & Manufacturing Company, and chairman of the executive committee of the National Industrial Conference Board, made a statement on the work of the Commission of Employers and Workers, of which he was a member representing the employers. The report of this commission was published in part in last week's issue, page 736. Mr. Osborne's statement follows.]

The significance of the agreement reached by the commission of employers and employees lies in the fact that in the face of a great national emergency two groups whose views have been popularly believed to be irreconcilable have met and by discussion and concession agreed upon a program that fully protects not alone the legal rights of both groups but the cherished principles for which they have most tenaciously contended.

The cardinal principle upon which the commission proceeded in its deliberations was that there must be no interruption to the production of war essentials by acts to prevent which lay within the control of either employer or employee.

This meant that for the period of the war there should be no lockouts or strikes.

If labor is to relinquish the principal weapon by which it has heretofore secured compliance with its demands, it becomes necessary that there be created a tribunal through which both the worker and the employer shall be guaranteed that every just grievance shall have a hearing and be settled fairly and in accordance with a body of agreed-upon principles.

This, I believe, the program insures.

If the leaders of labor throughout the country are, as I believe them to be, of the same high-minded and patriotic type as their representatives with whom I had the honor and good fortune to sit in conference, I am sure there will be no difficulty that the machinery provided cannot compose with impartial justice to all parties.

Speaking for employers, I am confident that they will whole-heartedly support the program agreed upon by their representatives. I have construed my presence on the commission and my agreement to the program as a pledge of the great national associations of manufacturers represented on the National Industrial Conference Board, which sent me there, that employers will observe the letter and spirit of the understanding.

I cannot express too highly my appreciation of the invaluable services rendered to the commission by the representatives of the public, ex-President Taft and Frank P. Walsh. Their counsel was of the utmost value to the other members in all of the difficult and complex questions that formed the subject of discussion.

Second only to the army of our brave fighting men is our great productive industry, and if we can maintain a condition of industrial peace at home through the medium of the agreement now reached, as I firmly believe we will, no American need doubt the successful outcome of our national effort.

Some Day The Fuel Question May Be Settled

—Knoxville (Tenn.) Tribune

SIGNALING APPARATUS WORK IN ASSOCIATED MANUFACTURERS

New Section Effects Further Organization by Appointment of Committees to Take up Activities in Many Lines

The Signaling Apparatus Section, which was formed recently in the Associated Manufacturers of Electrical Supplies, held its second meeting at the association rooms, New York, on April 5.

George L. Patterson of Stanley & Patterson, Inc., New York, is chairman of the section, with R. Edwards, Jr., of Edwards & Company, Inc., New York, secretary and E. Whitmore of the Manhattan Electrical Supply Company, New York, treasurer. The following standing committees were appointed in the section:

Committee on Annunciators.—E. Ward Wilkins, chairman, Partrick & Wilkins Company, Philadelphia; T. W. Ness, Holtzer-Cabot Electric Company, Boston; R. Edwards, Jr., Edwards & Company, Inc., New York.

Committee on Small Bells and Buzzers.—W. J. Tonkin, chairman, Ansonia Electric Company, Ansonia, Conn.; C. P. La Shelle, W. R. Ostrander & Company, New York; E. Whitmore, Manhattan Electrical Supply Company, New York.

Committee on Contact Devices.—E. Whitmore, chairman, Manhattan Electrical Supply Company, New York; W. J. Tonkin, Ansonia Electrical Company, Ansonia, Conn.; Albert S. De Veau, Stanley & Patterson, Inc., New York.

Committee on Fire Alarm Apparatus.—Vernon Durbin, chairman, Holtzer-Cabot Electric Company, New York; G. L. Patterson, Stanley & Patterson, Inc., New York; R. Edwards, Jr., Edwards & Company, Inc., New York.

Committee on Signal Gongs.—G. L. Patterson, chairman, Stanley & Patterson, Inc., New York; T. W. Ness, Holtzer-Cabot Electric Company, Boston; R. Edwards, Jr., Edwards & Company, New York.

Committee on Telephone Apparatus.—B. C. Rogers, chairman, Connecticut Telephone & Electric Company, Meriden, Conn.; A. S. De Veau, Stanley & Patterson, Inc., New York (one member still to be appointed).

Committee on Telegraph Instruments.—E. Whitmore, chairman, Manhattan Electrical Supply Company, New York (two members still to be appointed).

Uncle Sam Pays—Buy His Bonds

Membership Committee.—C. P. La Shelle, chairman, W. J. Ostrander & Company, New York; E. Ward Wilkins, Partridge & Wilkins, Philadelphia; M. J. McElroy, Holtzer-Nabot Electric Company, New York; B. C. Rogers, Connecticut Telephone & Electric Company, Meriden, Conn.; F. J. Tonkin, Ansonia Electric Company, Ansonia, Conn.

Another meeting will be held at an early date, when the various committees will have plans formulated for active work along the different lines already suggested. It is felt that this section will be a very important one in the industry covered.

ILLUMINATING ENGINEERING ACTIVE WAR SERVICE WORK In Many Ways the Society Has Aided the Government Since War with Germany Was Declared

A bulletin has been issued by the Illuminating Engineering Society telling in general terms of the war service work done by members.

As soon as war was declared the society offered its services to the government. Since then it has lost no opportunity to be of service. Its committee on war service, acting upon requests received directly or through the National Committee on Gas and Electric Service, has designed lighting installations for various departments of the government. The committee has also prepared a treatise on protective lighting at the request of government officials.

Members nominated by the society, constituting the divisional committee on lighting under the committee in labor, of the Council of National Defense, have prepared a treatise on industrial lighting for application wherever work is done under contract with the government. Lighting experts for each state in the Union have been selected to co-operate.

The National Research Council has availed itself of the services of the society's experts in prosecuting its researches on problems of lighting and vision. The society's membership has been classified so that the government may have ready access to lighting specialists.

Showing that light properly controlled is a very important instrument for winning the war, the society says:

"At the front or on the sea it reveals and locates the enemy, his works, operations, submarines. It also conceals our own operations by camouflage or glare. It conveys intelligence by signals, even in the daytime. At home it protects buildings, piers, bridges and other works; it speeds production and prevents waste. It prevents accidents which jeopardize life and material. It conserves eyesight; gives cheer and comfort to workers."

NATIONAL COMMITTEE ON PUBLIC UTILITY CONDITIONS

Action by Executive Committee of National Electric Light Association to Give Direction to Work Under Way

At a recent meeting of the executive committee of the National Electric Light Association it was decided that a committee of three members should be appointed to co-operate with similar committees of the electric railway and gas industries in the formation of a conference or joint committee to advise in regard to such utility problems of national interest as may be specifically assigned for consideration. This suggestion arises from the desire to give specific direction and authority to the work which is being done now by the National Committee on Public Utility Conditions, representing the N. E. L. A., American Electric Railway Association, American Gas Institute and National Commercial Gas Association.

President J. W. Lieb reported at the meeting that the association, in the referendum of the Chamber of Commerce of the United States on water-power development, has given its affirmative vote for the proposed legislation by Congress. The committee approved the action.

Twenty-seven additional central stations have been admitted as members, also 773 Class B members, 13 Class D members, 76 Class E members and 3 foreign members.

HIGHER RATES ARE NEEDED IN CALIFORNIA

Power Companies Ask Commission to Apply Increases to All Consumers, Instead of to Selected Classes

The application which is now pending before the California Railroad Commission for a 20 per cent increase of rates on electric service for industrial plants, irrigationists and commercial lighting has been amended by the appellants, who ask that the increase apply to all classes. All of the power companies serving central California districts are affected.

Attorney B. D. Marx Greene, representing sixty California cities, asked the commission to order cancellation of all special contracts between the Great Western Power Company and the Pacific Gas & Electric Company and preferred consumers.

Mortimer Fleishhacker stated for the Great Western Power Company that if the schedule rate were to be applied to holders of special contracts the company's income would be increased between \$100,000 and \$200,000 annually.

Public utility men should regard it as both a duty and a privilege to subscribe for Liberty bonds to the fullest extent of their ability. They know from their own experience that ready and ample capital is essential to efficient and quick results in large undertakings. Our government has on its hands the largest undertaking in its history. The abundance or lack of money will determine the assurance or the difficulty of the early fulfillment of its war program, the complete success of which is essential to the safety of our citizenship and the preservation of humanity in the world.

W. W. FREEMAN,
President Union Gas & Electric Company, Cincinnati.

PLAN TO INTERCONNECT PLANTS IN OHIO DISTRICT

War Industries Board Interested in Arrangement to
Effect Improvement in Power Supply for
Group of Cities

A report from Alliance, Ohio, indicates that the War Industries Board is working on a plan of tying in the central stations of Pittsburgh, Youngstown, Niles, Warren, Akron, Alliance, Canton and Massillon in order to insure continuous power for manufacturers of munitions and war materials in the district. Several of these cities are already connected by high-tension lines and the plan would provide for lines between the others mentioned. Army engineers, it is said, have about completed a survey of the cities and will report soon to the board.

The shortage in the district is placed at 125,000 kw., and it is said that several plants will be enlarged to meet this need. One will be the large plant of the American Gas & Electric Company and West Penn Power Company at Windsor, W. Va. In addition, the plant of the Doherty interests at Bolivar, Tuscarawas County, Ohio, is to be completed. The two will supply about 80,000 additional kilowatts.

Should the government demand additions to plants, it is supposed that some plan will be provided to furnish funds.

Invest and Do Your Fair Part

SERVICE CHARGE RATE IN STATE OF NEW YORK

Empire State Gas & Electric Association Anxious to
Prevent Public Misunderstanding Where This
Charge Is Introduced

The Empire State Gas & Electric Association has printed a booklet on the "Service Charge Rate," which it has sent to electric and gas companies in New York State.

A letter accompanying the booklet, signed by the executive committee of the association, says that on account of rising costs many companies are finding it necessary to increase their rates, and in this connection some have adopted a method of charge consisting of a service charge plus a commodity charge, while others now have the matter under consideration.

As this is a very important subject, affecting not only individual companies but the entire industry in the State, it was deemed advisable to prepare the general discussion of the service charge rate, to which very careful attention is requested.

The executive committee is deeply interested in this matter and in seeing to it that whenever a service charge rate is established the method of procedure shall be such as will not prejudice the public against the form of rate or prevent the company from being able to justify it before the commission.

On April 19, 1917, the committee after careful consideration passed the following resolution:

"Resolved, that the executive committee approve the plan of a demand, service or customer charge plus a commodity charge for gas and electric rates."

On Nov. 22, 1917, this resolution was expanded thus:

"Further resolved, that the inclusion of the service charge in any change of rates should carefully be specified to be based on costs properly entering into such charge, which costs have heretofore been inequitably and disadvantageously obtained through the commodity charge, and should not be included merely as a means to increase revenue."

The above amendment was occasioned by an apparent misunderstanding of the matter on the part of some companies, but in a number of recent instances the method of procedure employed by the companies in establishing this form of rate has indicated that, in spite of the above resolution, the subject is not yet clearly understood and that some further explanation is necessary in order that mistakes may be avoided.

The committee expresses the hope that the discussion will clarify the question, will encourage the adoption of this method of charge where the circumstances and conditions warrant, but will prevent its adoption without full ascertainment of the facts and a convincing explanation to consumers.

"Liberty or Death"—Liberty Bonds

GREAT PROGRESS BEING MADE IN ELECTROCHEMISTRY HERE

C. F. Burgess, Addressing Chicago A. I. E. E. and
Western Society of Engineers in Joint Session,
Tells of Accomplishments in the Art

C. F. Burgess of Madison, Wis., who is now spending much of his time as an electrochemist for the government at Washington, spoke before a joint meeting of the American Institute of Electrical Engineers, Chicago Section, and the Western Society of Engineers, on March 25.

The features of the address were the speaker's emphatic statements that wonderful progress is being and has been made by United States electrochemists since war began in spite of all enemy statements and inferences to the contrary, and his equally emphatic avowal of the necessity for more electrochemical work to win the war.

Choose the Best—Liberty Bonds

N. E. L. A., Pacific Coast Section

The joint convention of the Pacific Coast Section, N. E. L. A., California Association Electrical Contractors and Dealers, and the National Electrical Supply Jobbers' Association of the Pacific Coast will be held at Del Monte, Cal., May 9-11, 1918. As noted in the ELECTRICAL WORLD for March 23, this convention, which had been planned for April 24-27, was postponed to avoid interference with the Liberty Loan campaign.

Annual Meeting of Society for Electrical Development

The annual meeting of the Society for Electrical Development, Inc., will be held on Tuesday, May 14, at 11 a. m., at the offices, in the Engineering Societies Building, 29 West Thirty-ninth Street, New York.

San Francisco Electrical Development League.—At the luncheon of the league on April 3 Gen. C. A. Woodruff gave a talk on "How We Can Help."

Buffalo Engineering Society.—On April 17 the Buffalo Engineering Society will devote a meeting to discussions regarding electrical and chemical engineering subjects.

A. S. M. E., St. Louis Section.—On March 29 the St. Louis Section of the American Society of Mechanical Engineers elected Louis Gustafson chairman and J. P. Morrison secretary.

A. I. E. E., Portland Section.—At a recent meeting of the Portland (Ore.) Section of the American Institute of Electrical Engineers J. B. Fiskien talked on "Changes in Distribution System on Account of Range Load."

I. E. S., Philadelphia Section.—At a meeting of the Illuminating Engineering Society at Philadelphia M. Luckiesh of the Nela Research Laboratory, Cleveland, Ohio, gave an interesting talk on the "Esthetics of Street Lighting."

Jovian Electric League, Los Angeles, Cal.—At the March 27 meeting of the league E. S. Parker, manager of the Knox School of Business Efficiency and Salesmanship of Cleveland, Ohio, spoke on "Salesmanship That Concerns Everybody on the Payrolls."

Electrical Supply Jobbers' Association.—The date of the tenth annual meeting of the Electrical Supply Jobbers' Association at the Homestead Hotel, Hot Springs, Va., has been changed from May 28, 29 and 30, 1918, to May 21, 22 and 23, 1918.

Engineers' Society of Milwaukee.—At the April 10 meeting of the Engineers' Society of Milwaukee Charles L. Fortier, chief engineer of the Johnson Service Company, gave an illustrated talk on "Automatic Control Apparatus for Temperature Regulation."

A. I. E. E., Indianapolis-Lafayette Section.—E. P. Shepard of the Bureau of Standards delivered an address on "The Work of the Bureau of Standards," with special reference to electrolysis and its mitigation, before the Indianapolis-Lafayette Section of the American Institute of Electrical Engineers.

National Association of Electrical Contractors and Dealers.—The officers and executive committee of the National Association of Electrical Contractors and Dealers held a three-day session in Detroit on April 1, 2 and 3. It was attended by a large number of contractors from Detroit and the rest of Michigan, and also by a considerable number of important men in the electrical industry.

A. I. E. E. in Joint Meeting.—A very interesting meeting of all the engineering societies of San Francisco, consisting of civil engineers, mechanical engineers, chemical engineers, mining engineers and electrical engineers, was held recently. P. M. Downing, chief engineer of the Pacific Gas & Electric Company, delivered an address on "Interconnections of Power Plants," and D. M. Foulson talked on "Fuel Oil Saving."

Associations and Societies

A complete Directory of Electrical Associations is printed in the first issue of each month on the next-to-last text page.

Minnesota Electrical Contractors' Association.—Dean John R. Allen of the College of Engineering and Architecture, University of Minnesota, spoke on "Electrical Conditions in Europe Before the War" at the convention of the Electrical Contractors' Association of Minnesota. At the business meeting of the association it was decided that the old officers should remain in office until the regular meeting in June. W. L. Goodwin spoke on the Pacific Coast merchandising plan and answered questions concerning it.

Southwestern Electrical and Gas Association.—The annual convention of the Southwestern Electrical and Gas Association, to be held in Galveston April 15 and 16, as previously announced in the ELECTRICAL WORLD, will consider some vital problems which have been forced upon public utility plants by war conditions. The increased and still increasing cost of fuel, material and labor, the possibility in the near future that prices may be still further increased, and the inability on the part of the public utilities to obtain these commodities will be the more important subjects. Labor and the demands of the government in the matter of taxation on gross earnings and profits will also be discussed.

Oklahoma Gas, Electric and Street Railway Association.—The annual convention of the Oklahoma Gas, Electric and Street Railway Association will be held at Oklahoma City on April 22 to 24 at the Lee-Huckins Hotel. Among the interesting papers to be presented will be "Electricity in Oil and Gas Fields," by L. E. Mohrhardt, Southwest Gas & Electric Company, Oklahoma City; "High-Tension Transmission and Distribution," by Lee Boyer, Choctaw Power & Light Company; "Gas-Fired Boilers," by L. A. White, Muskogee Gas & Electric Company; "Present Trend in Rate Making and Valuation," by H. N. Strait, H. M. Byllesby Company; "Relations of Utilities to the Public," by A. L. Mitchell, engineer for State Corporation Commission; "Needed Utility Legislation," by Charles Hoopes, Oklahoma Railway Company; "Utility Taxation," by Prof. F. F. Blachly, University of Oklahoma; "Relations to Customers," by R. K. Johnston, Washita Electric Company, and W. J. Dibbens, Guthrie Gas, Light, Fuel & Improvement Company; "Oklahoma Utilities and War Problems," by Prof. L. W. W. Morrow, University of Oklahoma, and Guy B. Treat, Oklahoma Railway Company. In addition association policies for 1918 will be discussed and the question box will be opened. Officers will be elected.

A. I. E. E., Schenectady Section.—Lieut.-Col. Nugent H. Slaughter, Signal Corps, U. S. A., delivered an address on "Army Radio Communication" before the Schenectady Section of the American Institute of Electrical Engineers on April 5.

A. I. E. E., Toledo Section.—The regular monthly meeting of the Toledo Section of the American Institute of Electrical Engineers will be held at the Scott High School auditorium on Wednesday, April 17. E. E. F. Creighton will speak on "The Theory and Practice of Lightning Protection."

A. I. E. E., Utah Section.—John H. Lewis, state engineer of Oregon, delivered an address on "Western Development and Its Relation to National Transportation Policies," on March 20, before a joint meeting of the Utah Section of the American Institute of Electrical Engineers and the Utah Society of Engineers. He said that "only through development of hydroelectric resources on a vast scale, with the aid of the federal capital, will the United States be saved from industrial disorganization after the war." By means of electrification of the railroads at this time the transportation facilities of the country can be immediately organized on a war-time basis. The development of electrical energy in large centralized water-power or steam plants by the federal government and its sale at approximate cost in wholesale blocks at important industrial centers to run the railroads and industries of this country is a national economy. This must be worked out if the United States is to survive the bitter industrial war to follow the close of the present war.

National Electrical Contractors and Dealers' Association, Connecticut Section.—At a meeting of the Connecticut Section of the National Electrical Contractors and Dealers' Association on March 27 James R. Strong, chairman of the advisory committee of the national association, read several letters from some of the large manufacturing companies, pledging themselves to an established differential between the industrial plants and the contractor and jobber. Isolated plants and industrial plants are to pay the consumers' prices for electrical machinery and materials, and shipbuilding companies and construction companies of like nature will have to pay the contractor's price. It is thought by the association that this differential will have a favorable effect upon the industry as it means fair competition to the jobber and the contractor. At a dinner given by the association W. L. Goodwin gave a talk on the so-called Goodwin plan and answered questions about it. The meeting was presided over by the state secretary, George M. Chapman, instead of E. A. Francis, who was unable to attend on account of illness. The meeting was attended by all branches of the electrical industry, consisting of seventy-five contractors, fifty-two manufacturers' representatives, twenty-seven jobbers and nineteen central-station men.

Current News and Notes

Timely items on electrical happenings throughout the world, together with brief notes of general interest.

Municipal Capital Issues.—The capital issues committee of the Federal Reserve Board announces that, upon the recommendation of its advisory committee, in view of the large aggregate of municipal issues offered in relatively small amounts, it has decided to reduce from \$250,000 to \$100,000 the minimum limit on municipal issues upon which it will give advice with respect to the question of whether or not such issues at this time are compatible with the public interest.

New Hydroelectric Service Saving Coal.—By the shutdown on March 19 of the Margaret Street generating plant of the Springfield (Mass.) Street Railway and the operation on this site of a substation of the Turners Falls Power & Electric Company supplying the city lines through step-down transformers and motor-generator sets, a great improvement in service has been effected. The estimated saving in coal is 100 tons per day. Mayor Stacy, members of the City Council and of the Springfield Chamber of Commerce inspected the substation recently as guests of President C. V. Wood of the railway company.

Mountain States Power Company.—The Mountain States Power Company has acquired all the property of the Northern Idaho & Montana Power Company in Oregon, Washington, Idaho and Montana. The property operating as the Oregon Power Company, with headquarters at Eugene and Marshfield, Ore., will continue to operate under that title. The properties with headquarters at Kalispell, Mont., and Sandpoint, Idaho, will operate under the name Mountain States Power Company. The company will be under the operating direction of Elmer Dover, vice-president of H. M. Byllesby & Company, with headquarters at Tacoma.

Flatbush Electric Rates.—Figures tending to show that its operating costs have greatly increased within the past few months and that inferentially it is not in a position to offer reductions in its rates for electricity have been placed in evidence by the Flatbush Gas Company before the New York Public Service Commission for the First District. The occasion of their presentation was the rehearing granted by the commission upon its recent order directing the company to reduce its electric rates from a maximum of 12 cents to 10 cents on March 1, 1918, and to make other reductions to a maximum of 8 cents by March 1, 1919. The company has refused to accept the commission's order, and announced that it would demand a rehearing and would

take such steps as were possible to prevent the order from going into effect.

Radio Course in University of Pennsylvania.—The University of Pennsylvania is planning to add to the curriculum of the Electrical Engineering School a new course in radio communication especially adapted to fit students for enlistment in the Signal Corps of the United States Army. Announcement of the new course has just been made by Dr. Harold Pender of the faculty, and a large enrollment is anticipated. Upon completion of the course, students enlisting in this branch of service will be sent to special government schools for further training, where opportunities for qualifying as non-commissioned officers, with possible advancement to commissioned grades, will be afforded.

Men Needed in Ordnance Office.—Men are needed for the requirements section of the Control Bureau, Ordnance Office, War Department, of which section Lieut.-Col. M. C. Rorty is in charge. This section is charged with the responsibility of estimating quantities and delivery dates for all purchases of ordnance material, amounting to many hundreds of millions of dollars per annum. The men should be capable of analyzing a variety of facts in relation to the needs for such material and presenting sound conclusions as to the purchases that should be made. They should in general be college graduates and ordinarily should be men who ranked in college from a scholastic standpoint in the upper 25 per cent of their classes. The men should have had experience in preparing estimates or reports on which their reputation has rested and on the basis of which substantial money expenditures have been made.

Cincinnati Needs Amendment of Rate Agreement.—The Union Gas & Electric Company, Cincinnati, has sent to the Ohio Public Utilities Commission a motion to reopen its appeal from a city rate ordinance which was settled by agreement in February, 1917. President W. W. Freeman and Attorney Miller Outcalt first notified Mayor Galvin of their intention to do this unless some arrangement could be made to allow an increase over the present maximum rate, 8½ cents per kilowatt-hour. An ordinance fixing this figure was enacted by the council in 1915, and the company appealed to the Public Utilities Commission. Then a settlement was reached on the rate fixed by the ordinance. Mayor Galvin informed President Freeman that the city would oppose any change or increase. He said that the appeal, which was settled by agreement, cannot be legally reopened. The agreement provided that the above rate should continue for five years and that at the end of that time either side should have the right to an appeal from its provisions for the next five years, the contract covering ten years. President Freeman stated that the company lost several thousand dollars last year and cannot go on losing.

Recent Court Decisions

Findings of higher courts in legal cases involving electric light, power and other public utility companies.

Apparatus Must Prevent Injury to Customers During Lightning Storms.—A city furnishing light was bound to employ such approved apparatus in general use as would be reasonably necessary to prevent injury to a customer using its light arising from lightning conducted into residence, the Court of Appeals of Georgia held (94 S.E. 637). An amended petition in action for personal injury, based on incapacity of defendant's transformer to reduce primary current of high voltage so as to permit a safe current of low voltage to pass into light wires entering plaintiff's home, was held to state a cause of action.

Cost of Acquiring Customers in Valuation Proceedings.—Upon a valuation by the Public Utilities Commission, pursuant to the General Code, with a view to a city's use in the framing of a new ordinance fixing maximum rates following the expiration of an agreement between it and certain electric companies furnishing electricity in the city, the inclusion in the final valuation of an item scheduled as "costs of attaching business, \$375,000," conceded to represent the cost of acquiring customers, was erroneous, as, in view of varying circumstances which in advance would be purely hypothetical, the valuation was necessarily uncertain, theoretical and somewhat arbitrary, the Supreme Court of Ohio held in City of Cincinnati versus Public Utilities Commission of Ohio (118 N.E. 97).

Distance Between Tower and Telephone Lines.—That an electric company operating a power line and a telephone line constructed them as far apart as required by statute does not necessarily render it free from negligence in maintaining them at such distance, the Supreme Court of California held in Sickles versus Mount Whitney Power & Electric Company (170 P. 599). Where an electric company operating a telephone line and a power line knew of and consented to another company moving its telephone line to a position near its power line, it is liable for damage done by reason of their subsequently coming in contact with each other and burning a house. Where two electric companies are equally liable for damages done by wires coming in contact, one cannot complain that verdict was returned against it alone, because each was independently liable and the jury can find for one defendant and against the other. Where, by reason of negligence of an electric company, plaintiff's house was burned, the measure of damages by law was the value of the property destroyed.

R. W. Spofford, general manager of the Augusta-Aiken Railway & Electric Corporation, Augusta, Ga., who is a retired officer of the United States Navy, has been called to active service. W. C. Callaghan succeeds him as general manager. Mr. Callaghan has been with the J. G. White Management Organization, New York City, the operator of the Augusta company since 1913.

W. P. Southard, manager of the Albuquerque (N. M.) Gas & Electric Company, has been transferred by the parent company, the Federal Light & Traction Company, to Trinidad, Col., to manage the Trinidad Electric Transmission, Railway & Gas Company, succeeding E. C. Deal. Mr. Southard has been manager of the Albuquerque property for the last three years. Prior to that he was manager of the Las Vegas Light & Power Company, another company under Federal Light & Traction control.

Samuel W. Greenland, general manager of the Northern Indiana Traction Company and an electrical engineer of considerable prominence, has obtained a leave of absence in order to supervise the construction of a government power plant at Baltimore, Md., to be used in connection with a munition factory. The plant, it is understood, will have a rating of 20,000 kw. Mr. Greenland since the beginning of the war has taken a prominent part in his home city, Fort Wayne, Ind., in patriotic work such as Liberty loan drives, Red Cross campaigns, Y. M. C. A. work and boys' working reserves.

Weare Parsons, who has resigned as treasurer and manager of the Springfield (Ohio) Light, Heat & Power Company, has been engaged in public utility work since the very early days of telephoning. He began his career at Burlington, Iowa, in the early 80's. After spending approximately twelve years in the construction of telephone, electric light and street railway properties, during a part of which time he was with the Westinghouse Electric & Manufacturing Company's Chicago office, he joined the staff of the Western Electric Company. He remained approximately nine years with that concern, and for two and one-half years of that time operated an electric light property controlled by the Western Electric Company at Rutland, Vt., which was known as the Marble City Electric Company. Following that period he went to Joplin, Mo., in charge of the property of the Southwest Missouri Light Company, and for five and one-half years divided his time between that concern and the Keokuk Railway & Light Company of Keokuk, Iowa. Later he became connected with a Chicago bond house known as A. J. Whipple & Company. Leaving that concern, he was employed by the Springfield Light, Heat & Power Company, and during his seven and one-half years of service saw steady progress in the growth of that concern. He is at present enjoying a long-delayed vacation prior to taking up work again in the industry.

Men of the Industry

Changes in Personnel
and Position—
Biographical Notes

John R. Ruggles, former assistant electrical engineer of the Acme Power Company, Toledo, Ohio, is now general superintendent of the Durham (N. C.) Traction Company.

S. M. Moore, for the last six years on the staff of the New Haven (Conn.) office of the General Electric Company, has been appointed service manager of the power equipment department of the New England Engineering Company, Waterbury, Conn.

Samuel Insull, president of the Commonwealth Edison Company, received word April 8 of the death on April 5 of his mother, Mrs. Emma Insull, in London. Mrs. Insull was in her eighty-fourth year. She is survived by five children, Samuel and Martin J. of Chicago; Joseph, whose home is in Pittsfield, Mass.; Mrs. James McAdam and Miss Emma H. Insull of London. Prior to the war Mr. Insull was in the habit of visiting his mother from two to four times a year.

W. A. Brackenridge, vice-president and general manager of the Southern California Edison Company, Los Angeles, Cal., has been elected president of the company. Mr. Brackenridge, who is a well known hydraulic engineer, went to Los Angeles in the summer of 1909 to take the management of the predecessor company, the Edison Electric Company of Los Angeles. Prior to that he was a member of the advisory board of consulting engineers of the new barge canal in New York State.

Le Roy Clark, president of the Safety Insulated Wire & Cable Company and chairman of the Wire and Cable Section of the Associated Manufacturers of Electrical Supplies, has been appointed a member of the War Industries Board, of which he will be chief of the wire and cable section of the finished products division. This has necessitated the resignation of Mr. Clark as chairman of the war service committee of wire and cable manufacturers, although he will continue with official recognition the work he has been doing as chairman of this committee. All orders by the government and the Allies, and eventually, should conditions warrant, all commercial orders, for wire and cable henceforth will be placed before Mr. Clark for allocation among the manufacturers. Mr. Clark, who was born in 1872, upon graduation from Columbia University in 1894 in electrical engineering became permanently connected with the wire industry. He has always been in the employ of the Safety Insulated Wire & Cable Company, starting as electrical engineer in 1894 and becoming president of the company in 1906.

Obituary

George J. Jackson, president of the National Conduit & Cable Company, died on Monday morning of heart trouble at his home in New York City in his fifty-seventh year. Mr. Jackson has been prominently identified with the cable industry for many years, having been prior to that engaged in the wholesale dry goods business as an importer. His first connection with the wire field was with the Norwich Wire Company, a small concern which he had purchased. About twenty years ago this company was bought out by the National Conduit & Cable Company and Mr. Jackson was retained as secretary. He had continued in this capacity until last month, when he was elected president on the retirement of E. S. Perot.

R. W. Blackwell, president of R. W. Blackwell & Company and Johnson & Phillips, cable and electric supply manufacturers, London, England, died in that city on March 29. Mr. Blackwell was born in New York City on Jan. 27, 1858. He was educated at Andover Academy, Princeton, class of 1879, and Columbia Law School, class of 1881. He was associated with R. R. Hazard in the Gramme Electric Company, a combination of all the early electric companies. He was also associated with Mr. Hazard and with W. B. Parsons in the first proposed underground railroad in New York. He was one of the organizers in 1883 of the Bentley-Knight Electric Company, of which he was president. Mr. Blackwell went to England in 1888, where he formed the importing and contracting firm of R. W. Blackwell & Company, which built the first electric railways in England and equipped them with American apparatus.

Capt. Henry N. Brooks, a member of the United States Engineers Reserve Corps, whose death in France of pneumonia has just been announced in a cablegram, was prior to enlisting an electrical engineer with James N. Hatch, consulting engineer, Chicago. He went to France last December and was stationed in a small village as engineer depot officer, in charge of a large engineer supply depot for the United States Army. He was a graduate of the engineering college of Cornell University in the class of 1888 and was one of the pioneers in the electrical railway engineering field. One of his first jobs was as an electrical engineer on the electrification of the car lines in Philadelphia in 1892 and 1893. During his career he also operated an electric railway property in Florida and was at one time employed in electric railway work by the Westinghouse Electric & Manufacturing Company. He afterward had charge of the construction of the interurban line from Grand Haven to Grand Rapids, Mich. He was for eight years electrical engineer for the firm of Sargent & Lundy of Chicago. He had been with James N. Hatch for two years prior to his enlistment in the army last June. Mr. Brooks's father was the late Admiral William B. Brooks, U. S. N.

TRADE & MARKET CONDITIONS

News of the Trade for the Manufacturer, Wholesaler and Jobber
of Electrical Equipment and Supplies—
Notes on Industrial Activities and Business Methods

TRADE PROTECTION IS GROWING IN THE EAST

Preferential Discounts and Quantity Discounts
Together Are Expected Materially to
Strengthen Trade Distribution

Quantity purchase discounts have for a long time been used in the electrical jobbing field, but not too closely adhered to. There has been the old-time conflict between preferential or protective discount on the one hand and quantity discounts on the other. At the present time, however, the tendency seems to be firmly toward a strict adherence to the quantity purchase plan together with a trade preferential.

It has long been felt that retailers in the trade had been receiving a discount on purchases so small that they amounted to nothing more than retail transactions. There is a growing conviction that the contractor-dealer is not entitled to a discount unless he purchases in discount quantities; that he is not really a merchant unless he accumulates a satisfactory stock; that unless he can purchase in standard package quantities he is not big enough to be classed with contractors. Consequently the often expressed wish that contractors should pay retail prices for retail quantities seems about to bear fruit.

In wholesale purchases, however, a number of jobbers and a few manufacturers in the East have already notified the trade that quantity purchase discounts will prevail with a trade differential in the neighborhood of 10 per cent between contractor and all others.

This is but a beginning, and if it has the desired effect of strengthening the merchandising side of the contractor there is every reason to believe that a better preferential might result. The contractor to-day has practically nothing to do in the construction line and consequently is in an excellent position to give attention to the retail side of electrical merchandising.

Money Points the Way to Victory

TO PREVENT CONFUSION
IN GOVERNMENT ORDERING
Requirements Division Created to Collect All Purchasing Information, with Special Sections for Separate Commodities

A new plan of organization of the War Industries Board has been undertaken, the general purpose of which is to prevent confusion and conflict in the ordering and delivering of supplies and to secure unification of the government's policy in dealing with industrial problems. The essential change involved is the creation of a requirements division to which will be furnished information on all contracts, purchases and deliveries, and to which the supply divisions of the purchasing departments and the Allied Purchasing Commission will as far in advance as possible submit statements of their respective needs for raw materials and finished products.

To take charge of particular problems of supply there have been created special commodity sections, and whenever necessary to handle raw materials or finished products of which there is an actual or threatened shortage or the price and production of which should be controlled new sections will be created by the chairman of the War Industries Board. It is the purpose of the chairman of the War In-

dustries Board to make each of the section heads the sole government agency for dealing with the industry for which his section is responsible.

The chief of the commodity section will study the problem referred to his section and will procure from all available sources, including the supply departments, information and data which will be helpful in the allocation of these requirements. At meetings of the commodity section the allocation of materials or facilities to meet the requirements will be determined, and in this distribution the representatives of the various supply departments of the government who are members of the section will have full share.

In addition to dealing with problems referred to them by the requirements division, the commodity sections will have certain definite functions. The first will be the collection of information regarding industrial conditions already mentioned. Further, they will consider from time to time the extent of the existing sources of production, the creation of new facilities, the disclosure—if necessary, the opening up—of additional sources of supply, and the conversion of existing facilities to new uses.

Each commodity section will consider market conditions pertaining to the materials or commodities over which it has jurisdiction and will, where deemed advisable, recommend purchase plans to the several purchasing departments. In cases where it becomes necessary to control an industry in whole or in part by means of allotments, the appropriate section will determine the allotments of materials, commodities and facilities to the several departments of this government and to its allies, and also the extent to which manufacturers and others, whether serving the civilian population or engaged in the manufacture of war supplies, shall be supplied.

Back Up the Boys—Buy Bonds

TRADE ACCEPTANCE PLAN
OF CREDIT INDISPENSABLE
Its General Adoption Declared Necessary in Order
to Keep Commercial Credit in State of Fluidity
and Usability

In an address before the United States Chamber of Commerce convention on Thursday of this week Lewis E. Pierson, chairman of the board of the Irving National Bank, New York City, spoke on trade acceptances, giving opinions arrived at by the American Trade Acceptance Council. The following is quoted from Mr. Pierson's address:

"We believe, and feel prepared to prove, that in the intelligent and consistent use of this method is to be found the possibility of relief from most of the business absurdities and weaknesses which appear inherent in open account procedure.

"We find upon the testimony of hundreds of business men of highest standing, experienced in the use of the trade acceptance method, that obligations expressed in this form almost without exception are paid promptly at maturity.

"Were there no other consistent trade acceptance merits beyond this, and we have discovered many, still we would feel fully justified in appearing before this body and recommending the maximum of activity in the interest of substituting live, liquid, written, respected trade acceptances for the indefinite, imperfectly expressed and casually treated open accounts so common at present in American business.

"To the seller of merchandise we would say that the trade

acceptance is calculated to protect his proper interests to the fullest extent—that it carries with it a definite promise to pay, an acknowledgment of the correctness of deliveries, a shorter term of credit, greater flexibility of assets, better facilities for collection, a logical and improved relationship with customers and practical relief from expensive and burdensome practices which have grown up under the open-account method.

“To the buyer of merchandise we would say that the trade acceptance operates to his distinct benefit—that it gives to him classification as a preferred customer, one who serves notice upon the business world of his disposition and ability to meet his obligations promptly at maturity; that it gives to him greater independence of action; that it provides an effective check against overbuying and overborrowing; that it tends to establish his standing with banks and in the discount market and provides for him a substantially increased field of operations.

“To the nation and to all those properly interested in protecting its interests in the present grave emergency in history we would say that the development of the trade acceptance method in American business is not only important and urgent but indispensable. If we are to win this war and protect the national interest in the world commercial contest which will follow, we must put the business of the nation upon a sounder basis. Not only must our soldiers and sailors fight and suffer and citizens of all classes serve and sacrifice, but the American business man, in his particular field of service, must so direct his energies that this great resource, intrusted to his keeping—the commercial credit of the nation—will be kept in such a condition of fluidity and usability that to the fullest possible extent it will serve as an unshakable foundation upon which can be based the greatest effort of the greatest nation the world has known.”

METAL MARKET SITUATION

Higher Prices for Wire Products Freely Predicted—Persistent Efforts to Increase Official Rate

An intimation is going the rounds of jobbing circles that bare copper wire, rubber-covered, cable and weatherproof, may be advanced in price. The copper market is said to be tightening, and therefore a higher government rate will be urged to meet the so-called extra cost of refining and other overhead expense. Instead of the official selling figure for ingot copper being 23.50 cents, advocates of a higher price say it ought to be 25 cents flat. Should this argument prevail, naturally all wire products would follow suit, and while May 30 is the date when the existing price expires, an effort is evidently being made to discount the future. Insiders declare that this is the real reason of the talk about an advance. An authority disputes the necessity of increasing the current cost of the metal by saying, “A good many things may happen to the copper situation between now and June 1, but they will have to be very different from the present comfortable position of supply, demand and profits, we think, to justify higher prices.”

THE WEEK
IN TRADE

EXCELLENT business in electrical equipment and staple merchandise is the tenor of advices from various parts of the country. To be sure, purchases and specifications for government work continue to lead the market, but the entire trade is participating in these requirements. Stocks have been depleted and the backward freight deliveries are not easing the situation. Conduit is short everywhere, and there is a strong demand for pole-line material, copper wire, sewing and washing machines and general household electrical appliances. Price changes are announced by individual firms on a number of items. Scarcity of skilled labor is a cause of anxiety in manufacturing centers.

Business is being carried along on a smaller margin of profit than in former years, but it appears to be satisfactory nevertheless. Collections are excellent, in some sections surprisingly good, while fair on an average everywhere. Credits receive close attention.

NEW YORK

Commercial business with the jobbers is not so brisk; in fact, some houses frankly state it is rather flat at present. The government requisitions for all kinds of electrical goods—large and small orders for quick delivery—however, reflect a stage of activity more than compensatory for loss of sales in the regular trade channels. While no special pinch is felt for goods, the orders on manufacturers are no longer small. In certain lines either a full case must be taken or no goods are shipped. The “twelfth part of a dozen” practice, to use the expression of several jobbers, has been abrogated.

Deliveries on commercial orders are not getting better, but going from bad to worse. Jobbers are trying various expedients to place goods in the hands of the dealers in the quickest possible time.

Financially the trade is in a stronger position than for some time, collections growing better with the opening of spring business. The careful scrutiny of credits is maintained rigorously.

LAMPS.—Until further announcement import licenses will be denied on electric lamps. The import trade is very light at present, anyway, less than \$4,000 worth coming in in January. The owners of the tungsten lamp patent, on winning their infringement suit, refused to license imported infringing lamps other than those in stock at the time.

HOUSEHOLD SPECIALTIES.—Dealers are said to be stocking up liberally on sewing and washing machines in anticipation of a rapid movement during the late spring and early summer. The price increase of from 10 to 12 per cent which was put into effect April 1 by one concern affected ironing and washing machines, flatirons, glue pots and soldering irons. Deliveries on all this merchandise are from twelve to fourteen weeks behind, and distributors specially interested declare shipping conditions are growing worse.

RADIATORS.—The sharp demand has been caught up with, and surplus stocks are not infrequent.

CONDUIT.—Difficult as it is to get conduit from the mills at Pittsburgh and Youngstown, Ohio, a carload reaches its destination occasionally. It is of little relief to the market, however, and stocks continue low.

SOCKETS.—Though stocks on standard sizes have greatly improved, shipments from the Western manufacturing centers are behind six and eight weeks; New England points, ten days to two weeks. Express facilities are rapidly equaling freight delinquencies, which is partly due to the government commandeering many of the companies' special cars. Some jobbers are meeting the emergency by splitting packages and using parcel post. One large manufacturer states

that, whereas his company was four weeks in arrears on shipments, now an order can be filled and forwarded within a week.

PORCELAIN.—The new price list foreshadowed recently is expected to go into effect about April 15. Stock is difficult to obtain on account of the embargoes, word being received that an ample supply is ready for shipment from the factories. No curtailment of manufacturing has occurred. Jobbers claim to be paying a higher price for porcelain than the government, one leading manufacturer stating that his primary bid was promptly rejected on specifications submitted, with the intimation that unless the prices were reduced the War Industries Board would take over the plant and run it on a "cost-plus" basis. The producer succumbed to the inevitable.

DRY BATTERIES.—The factories are behind on orders, owing to the unusual demand, which is occasioned by jobbers and dealers doubling their requirements on the "safety first" plan. A dealer customarily carrying a dozen batteries on re-ordering increases it 100 per cent, with the jobber following suit to meet his trade's specifications. This occasions the congestion at the factories, which are further handicapped by an acute labor shortage.

REFLECTORS.—An ample supply is reported with no change in prices.

COLLECTIONS AND CREDITS.—Judging from statements of credit managers, collections are holding up, and bills are met with reasonable promptness. This is further proved by the gradual tightening of credit accommodations.

BOSTON

The tide of electrical activity shows little sign of receding, although business is reported to be somewhat quieter in sporadic instances. Jobbers with numerous connections and established in the larger centers are in general very much rushed with orders. Stocks are on the whole in good shape to meet the spring demand, and firm prices insure stable profits under good management. Collections are very fair indeed, despite the dominating influence of the third Liberty loan upon capital outpouring. Jobbers are feeling the shortage of skilled labor not a little, and it would seem that the wider utilization of women in this branch of the industry cannot long be deferred. The expected improvement in freight deliveries on the railroads materializes very slowly. The trade acceptance idea is also slow in gaining ground, especially in the interior. Experience is favorable toward the more extended use of this method of handling credits. It is reported that the National Army cantonment at Camp Devens, Mass., will be enlarged to about double its present troop capacity this year. This, with the army base for which plans are being pushed at Boston, is occupying the attention of the trade.

STORAGE BATTERIES.—Business is excellent, especially in units for automobile service. An enormous trade in second-hand and rebuilt automobiles is getting under way in Massachusetts this year, and more cars are registered than at this time a year ago. Express shipments from Eastern factories are now on a very satisfactory basis, deliveries of three or four days from New York City being not uncommon. No recent price changes are in evidence.

SEWING MACHINES.—Central stations are making a vigorous drive in sewing-machine motors, and the public is responding well. The deferred-payment plan seems to do away with the price question.

FANS.—The large jobbing houses are accumulating fans very rapidly now, and dealers are stocking up fast for over-the-counter deliveries. One of the larger houses has now received 4500 fans out of a total of 5000 ordered, and the next warm spell will find the dealers well prepared to meet the public demand. It is expected that there will be an unusually big sale this summer of the lower-priced fans.

ELECTRIC STOVES.—Interest is growing rapidly in electric cooking, and the smaller, portable stoves are moving unusually well. One central station now has 2000 electric ranges in its territory and has sold 300 of the smaller outfits within a year. Emphasis upon the coal-saving and

food-saving advantages of electric cooking makes a patriotic appeal to which many prospective customers listen intently at this time. In suburban towns where no gas supply exists the smaller electric ranges and stoves are arousing unusual interest.

WASHERS.—It is rumored that a price advance may be expected soon on washers. Trade is good in this line.

MOTORS.—Stocks of the smaller sizes tend to increase and prices remain steady. A few of the larger units are now to be found here and there.

CONDUIT.—Some improvement in deliveries from Ohio mills is reported, and "pick-up" shipments from Boston stocks are reported to be fairly prompt to the interior.

APPLIANCES.—Irons are moving well. Portable lamps are very quiet, although good stocks are on hand. Prices are in many cases attractive, and some extra business for summer homes is always in sight at this time.

LAMPS.—Stocks are increasing steadily.

MOTOR-DRIVEN CASH REGISTERS.—These labor-saving equipments are moving well, one Boston department store having purchased over \$100,000 worth in the past year with an increase in clerical efficiency of about 20 per cent compared with former cash-carrier methods.

CHICAGO

A checking up of jobbers' business for the first three months of 1918, as compared with the same period last year, shows that the gross on the average was practically the same. It is said, however, that the 1918 business is not a good business. There is less profit in it than there was in the same period of last year, and it is not of the same steady character. One jobber described it as an "accidental" business, meaning that its spotty character as seen in the retrospect made it seem only an accident, caused by a large order or a good week here and there, that the total is as high as it is. The business this last week has been generally quiet. Among the contractor-dealers considerable interest was manifested in the news carried by word of mouth from New York that one large company had rearranged its schedule of discounts in favor of the contractor-dealers in the New York territory.

CONDUIT.—The industrial-plant demand for the larger sizes continues exceptionally strong. There was some relief in the delivery situation this week, but not enough to permit stocks to be replenished.

COPPER WIRE.—Jobbers report it impossible to keep a stock of any type of wire used by industrials. The demand is strong and very steady. Prices remain unchanged, with a slight weakening in discounts by some manufacturers.

TAPE.—An increase in prices has been announced which amounts to about 20 per cent. The higher price of cotton and rubber are given as causes.

PORCELAIN INSULATORS.—High-tension equipment continues to move with rapidity. There are no orders for new lines, but the business for replacements on present lines does not look like small business when it persistently comes in in lots of 50,000 items. Recent factory shipments to France have also helped to hold up the total volume.

ELECTRIC RANGES.—Certain sections of the West are ordering in large quantities. The small-town demand continues strong, with continual evidence that small companies which never before sold ranges are going into the field.

INCLOSED FUSES.—Some manufacturers have recently rearranged their schedule of discounts to protect the contractor-dealer. Certain concerns in the field had been using a schedule of this sort for some time. Such a plan, of course, made it necessary to give the jobber a better price. This recent change has given the jobber a better price by from 5 per cent to 10 per cent. There is no change, however, in the price of fuses to the consumer.

DOMESTIC APPLIANCES.—The market in 32-volt electrical appliances is very active. Manufacturers of 32-volt equipment are finding farm lighting plant manufacturers and distributors very ready to line up with them in the distribution of this merchandise.

ATLANTA

Although the federal government's Capital Issues Committee has passed upon about a quarter of a billion of securities so far, the issues in question covered refunding purposes and no visible effect is felt in this section at present. Residence construction is moving along fairly well in Atlanta, but there is more or less uncertainty in the Southeast regarding the Fuel Administrator's order covering the clay industries. The consensus of opinion is that these products will advance 25 per cent, in view of the curtailment, which will be reflected in building operations. Word has been received to the effect that the Terry Shipbuilding Company, Port Wentworth, Ga., will construct two floating dry docks at a cost of \$2,000,000.

The demand for all staple lines is holding up well and considerable improvement is noted in deliveries generally.

POLES AND LINE MATERIALS.—There is a steady demand for poles, and deliveries are much better. Prices remain the same. Sales in hardware continue good. Deliveries have been reduced to four weeks. The demand for carload lots of cross-arms has decreased, but the less than carload lot requirements have increased about 400 per cent. Considerable difficulty is experienced in getting the railroads to accept shipments of this class, and deliveries are being made in approximately three months. Prices advanced 10 per cent April 1. The sale of insulators continues steady in the face of a 10 per cent increase and poor shipments.

CABLE.—The transportation situation is affecting shipments, but on the whole deliveries are slightly better.

TRANSFORMERS.—Although the demand from central stations for capacities up to 25 kva. has fallen off, the volume of business is holding up well when government purchases are taken into consideration. Stocks are getting in better shape. The delivery on the power type is improving.

PANELBOARDS.—This line continues strong, the volume of business being satisfactory. Deliveries are coming in from two to three weeks.

SEATTLE

The feature of the past week's business was the placing of a large order for power apparatus in the Portland territory and the continued movement of floodlamps and sewing machines. During the past month several large orders for power apparatus in the Portland and Gray's Harbor fields have been placed by shipyards, but the last order was considerably heavier than the preceding ones. The buying of electrical apparatus and equipment in the Puget Sound district continues with steady volume. Last week showed a noticeable increase in government buying for navy yard and cantonment work.

A recent order was placed for floodlamps for both the navy yard and the American Lake cantonment, also for a considerable amount of house-wiring material and matter listed as pick-ups. An inquiry was received in Seattle for 400 washing machines for the Montana territory. Washing-machine and other domestic appliance sales are keeping up well. Irons and ranges are expected to begin a sharper movement with the approaching summer. The conduit situation is again causing much concern. Recent shipments, consisting of several carloads, relieved the situation temporarily, but the available supply is practically exhausted. Eastern manufacturers cannot obtain closed cars to make shipments. The shortage of rubber-covered wire in the larger sizes, of porcelain, of the larger motors and of certain sizes of lamps has not been relieved to any extent. Prices remain practically the same. Several large credits are in the process of being placed in the Seattle territory for shipbuilding enterprises. Collections are excellent. A Seattle shipyard recently signed a contract for constructing six submarines for the United States government. By-products factories of various kinds are in prospect for immediate establishment in Seattle and contiguous territory. Electrical jobbers are in receipt of inquiries for electrical equipment for several wood by-products plants, including corks, lignum, cellulose, wood alcohol, wood flour, fir oil, etc.

Dealers report that sales of house-wiring devices are well sustained, and fixture sales show a noticeable increase over the past two weeks. Jobbing and factory propositions are receiving favorable consideration in the Spokane field, and it is believed that Spokane is on the eve of an important industrial expansion. The total of elevators already up, contracted for or under construction in the Northwest—Washington, Oregon and Idaho—is placed at 200 to date.

Douglas fir lumber is specified by the government for the frame superstructures of 100,000 new freight cars. Car builders of the Northwest are trying to land a portion of the car-building contract. Shops in Portland, Seattle and Tacoma assert they are equipped to handle 10,000 cars within a specified time. The car supply at the West Coast mills is slightly improved, although a permanent improvement will not result until it substantially exceeds the volume of production at the mills. Railroad and steamship companies are slowly reducing the amount of accumulated export freight in Seattle's yards and docks. Freight conditions are deplorable, with no immediate signs of improvement.

SAN FRANCISCO

The past week has been a quiet one for the electrical industry, and this condition will doubtless continue during the course of the Liberty loan drive. In deference to this campaign, the National Electric Light Association convention at Del Monte, which was to be held in April, has been postponed to the second week in May so as not to interfere with the patriotic efforts of the delegates.

There is little new building reported, the outstanding features being the awarding of contracts by the Pacific Gas & Electric Company for the extension of its transmission lines to Guinda, Rumsey and Brooks and by the Pacific Telephone & Telegraph Company for a six-story class A building in Oakland and several street railway extensions in San Francisco. The scanty snowfall of last winter is reflected by the construction of a third reservoir on the Stanislaus River by the Sierra & San Francisco Power Company and a planned interchange of power between the San Joaquin Light & Power Corporation and the Mount Whitney system, which have tied their power transmission lines together at Strathmore. San Francisco building permits for March, 1918, totaled 380, costing \$758,000, as against the respective figures of 597 and \$2,040,000 for March, 1917.

No general statement can be made that will adequately cover credit conditions, for they vary with different classes of customers. They can be approximated by the assertion that collections from dealers and contractors are surprisingly good, but that payments on work and material for industrial plants are quite slow. In the opinion of shrewd credit men the reasons for this state of affairs are plain—first, that electrical dealers are no longer inclined to recklessly take work without regard to the credit risk; second, that on account of widespread industrial work retail money is plentiful and payments are prompt to dealers; third, that a great deal of this industrial work is for the government, whose routine for payment takes time and slows up successive payments; fourth, that there seems to have been a wave of slower conditions that was first noted in New York two months ago and has gradually spread West.

Staple material is found to be ready for factory shipment in a far shorter time than during the first two months of the year, although it is almost impossible to get special material. The strenuous efforts of the various car conservation committees have resulted favorably, but the time in transit is still unimproved, forty-five days for carloads and from fifty to sixty days for less-than-carload shipments being the average.

LAMPS.—Deliveries are better and business still holds strong. The customary summer let-up will be welcome this year, as it will enable dealers to catch up on their back orders, and the 10 per cent increase in the price of lamps will more than care for any lessened consumption due to the new daylight law.

MOTORS.—Stocks are good and deliveries fair, with a steady demand for 2-hp. to 5-hp. sizes and an increased call for 20-hp. to 50-hp. sizes, some of which is due to the opening of new mines.

Current Prices of Electrical Supplies

New York and Chicago Quotations

THE prices quoted are those prevailing in standard packages of specified lots on apparatus and appliances in Eastern and Middle West markets at the beginning of business on Monday of this week. They are in all cases the net prices or prices subject to discounts from standard lists of contractors, central stations, dealers and others engaged in the resale of such goods.

Prices in Southern and other nearby markets will rule about the same as those in the Middle West, although slight modifications to cover increased freight and local demands should be expected. In the Far West and on the Pacific Coast the prevailing prices are naturally higher, covering as they must increased

freight and the necessity of larger stocks with increased interest and warehouse charges on account of the distances from sources of supply, infrequent turnover of stock and uncertainty as to delivery of goods in transit. Moreover, the Far West presents a wide variation in demand due to a small population spread over a wide area in agricultural and mining communities, as contrasted with the denser population of the East and Middle West, their nearness to the sources of supply, the more frequent turnover in stocks and the constant demands which arise in industrial centers. Price variations may be due to difference in grade of products of different manufacturers, to local conditions, or to both.

NEW APPARATUS & APPLIANCES

A Record of Latest Developments and Improvements in Manufacturers' Products Used in the Electrical Field

Weldless Guy-Rod Head

The Diamond Expansion Bolt Company, 90 West Street, New York City, has developed a new guy-rod head shown in the accompanying illustration. It consists of a weldless loop constructed so that a square-headed rod can be slipped through it and held in position against turning. The weldless

GUY-ROD HEAD ALLOWS NATURAL BEND
FOR WIRE

eye is shaped so that the wire looped through it will not be bent in too small radius. Another advantage lies in the fact that there are no screw threads above the ground level to deteriorate from atmospheric conditions.

Portable Commutator Slotting Machine

A new and simple slotting machine for undercutting mica in commutators is being manufactured by F. E. Aurand of 123 South Cuyler Avenue, Oak Park, Ill. The machine consists essentially of a head which contains a small circular saw attached to a transverse shaft carrying a worm gear, and a hollow handle which contains the worm shaft and a small motor. The service wires for the motor enter through the outer end of the handle.

The device can be used for all sizes of commutators and can be adjusted to cut at various depths. A thin guide shoe slides in the slot immediately behind the cutting saw and greatly aids in holding the saw in its proper plane.

MACHINE SLOTS COMMUTATORS WITHOUT
REMOVING BRUSH RIGGING

One of the principal advantages lies in the fact that most commutators can be undercut with this device without removing the brush-holder rigging. On small machines it may be necessary to

remove one set of brushes, but on most large machines no dismantling is necessary. By using care in the selection of properly gaged saws the manufacturer claims that mica can be cut as clean as by a milling machine.

The small motor contained in the handle is of the universal type. Machines which will be operated by means of a flexible shaft instead of the motor will be built if customers desire. The hollow handle is made of cast aluminum and the complete outfit weighs about 11 lb. (5 kg.). Its simplicity and the ease with which inexperienced mechanics readily learn to operate it are among the features claimed for the device.

Portable Electric Sewing Machine

A light, compact sewing machine has been placed upon the market by the Triumph Specialty Company, 235 Canal

ENTIRE OUTFIT CAN BE EASILY CARRIED

Street, New York City. The device consists of a sewing-machine head, a motor, a speed regulator and a cover. The whole outfit can be packed inside the cover, and is so light that it can be easily carried and placed out of the way when not in use. Power is supplied by a Westinghouse "sew-motor" designed for 115-volt direct-current and 110-volt alternating-current circuits. The machine and motor are directly connected by a belt, which, it is claimed, insures quiet operation. The motor is controlled by a foot-operated speed regulator which provides any speed from one to several hundred stitches per minute. It is made of heavy steel and well insulated, being connected to the motor by a reinforced flexible cable.

Small-Size Warming Pad

The Westinghouse Electric & Manufacturing Company of East Pittsburgh, Pa., has placed on the market a 9-in. by 12-in. (22.8-cm. by 30.5-cm.) warm-

ing pad. The pad is similar to the standard 12-in. by 15-in. (30.5-cm. by 38.1-cm.) pad manufactured by the same company. It is equipped with two thermostats which are inclosed in the pad. These thermostats are connected in series and prevent overheating by opening the circuit when the temperature rises to a point near the maximum safe value. When the temperature falls the thermostat will reclose the circuit and thus maintain the heat at a uniform temperature. The pad is manufactured in one style only for a voltage range of 95 volts to 125 volts, and the power demand is 48 watts at 110 volts.

Combined Air Compressor, Buffing and Grinding Head

The United States Air Compressor Company, Cleveland, Ohio, has placed upon the market a combination air compressor and grinder outfit which is especially suitable for service in garages and similar places where compressed air is required. The outfit, driven by a 1-hp. Robbins & Myers motor, consists of a self-oiling air compressor with filtering trough, safety valve, buffing head and pressure tank with accessories. The air compressor is air-cooled and is designed for pressures up to 300 lb. per sq. in. (21 kg. per sq. cm.). An extra tank is provided to allow the motor to start against no pressure and obtain momentum before any load is applied. When the air in the main tank is raised to the proper pressure the automatic switch stops the motor and operates an automatic pressure release which

AUXILIARY TANK ALLOWS MOTOR TO GAIN
SPEED BEFORE ASSUMING LOAD

opens the tank to the air. The rating of the motor is sufficient to allow the use of the buffing and grinding outfit at the same time the air compressor is working.

Concealed-Terminal, Fuseless Cleat Rosette

Pass & Seymour, Inc., Solvay, N. Y., have placed upon the market a concealed-terminal, fuseless-cleat rosette with a pivot cap. The rosette is of special rugged construction and is designed to carry the wires a full half inch (1.27 cm.) from the surface wired over. The binding screws which secure the cap to the base are so arranged that the cap may be pivoted on one end while the other end of the cap, when the binding screws are released, swings in or out of position. This feature makes it easy to wire the rosette at a bench or on a step-ladder.

Electric Iron with Switch Plug

Landers, Frary & Clark of New Britain, Conn., are marketing two 8-lb. (2.7-kg.) electric iron models equipped with permanently attached push-button switches. These switches are conveniently arranged on the iron so that they can be controlled without moving the hands from the iron handle. A quick double-break switch of simple construction is inclosed in a heavy split casing held together by a steel clamp which also serves to attach the plug to the handle bracket. It is claimed that the use of this switch lengthens the life of the cord, saves energy, and is advantageous because of the fact that it eliminates the arc which would ordinarily occur when the commonly used plug is removed from the iron.

Push-Button Switch with Automatic Time Regulation

The accompanying illustration shows a switch that can be closed by direct or remote control and will stay closed for

ADJUSTABLE DASH-POT CONTROLS THE TIME

a predetermined time. The connecting operation is accomplished by pressing the button at the top of the switch or by working a device on the opposite side of the room that is connected to this

button by means of a steel wire. An adjustable dash-pot limits the time during which the circuit remains closed. This time limit can be varied from a few seconds to a ten-minute interval. If it is desired to close the switch for an indefinite period the black button marked *E* is pressed upward. To open the circuit the same button is pressed down. The device is useful for installations of porch and basement lamps, and in many halls and garages. It is claimed that the device is economical because its action is positive and there is no chance of the lamp burning unintentionally after the predetermined period. It is being marketed by Samuel M. Esler, 59 East Adams Street, Chicago.

Adapter for Changing from Direct to Indirect Lighting

The accompanying diagram shows a method of adapting diffusing bowls to old lighting fixtures having standard fittings. The adapter makes it possible to use the flat-type doric moonstone or other direct-lighting reflector styles of shades with gas-filled lamps for indirect lighting. This adapter consists merely of three chains with spring clips at the lower end and a shade fitting at the

SPRING CLIPS THAT ARE EASILY REMOVED FROM BOWL FOR CLEANING

upper end. The upper end is attached to the shade holder of the original unit and the lower spring clips are attached to the diffusing bowl. The spring clips can be easily attached to the bowl but cannot slip off accidentally. By using these adapters an even pull is exerted on the diffusing-bowl rim and the bowl does not have to be lored and thus weakened. This device is manufactured by the Lighting Studios Company, 220 West Forty-second Street, New York City.

Household Steam Laundry with Facilities for Inspection

The accompanying illustration shows a motor-operated "Almetal" household steam laundry marketed by the Manufacturers' Distributing Company, Fullerton Building, St. Louis, Mo. The machine, which is gas-heated, boils, washes and sterilizes fabrics in one operation by the vacuum-suction system. It forces boiling soapsuds through the clothes, heats the water in the machine, and keeps it boiling until the washing oper-

ations are finished. Inspection of the clothes in this machine is facilitated by a device that automatically lifts the clothes out of the hot water. If they are found to be clean they can then be

CLOTHES AUTOMATICALLY LIFTED OUT OF WATER

run directly through the wringer. The washing machine is of metal construction throughout and is operated by a 0.25-hp. Robbins & Myers waterproof motor.

Gothic Lantern

The National X-Ray Reflector Company, 235 West Jackson Boulevard, Chicago, has placed on the market a new Gothic lantern that is adapted for use in a building decorated in Gothic style. The fixture is made of "compone" in a variety of finishes with either opal or colored glass panels. The lantern can be used for luminous indirect, indirect or direct lighting, and is especially desirable for use in churches, clubs or public buildings.

Expansion Joint for Pipe Line

A device that, it is claimed, eliminates pipe-line expansion difficulties is being placed upon the market by the R. D. Nuttall Company of Pittsburgh, Pa. The expansion joint is made of one piece of material, machined inside and out from a solid forged-steel blank which is oil-tempered. The corrugations allow expansion or contraction by an action similar to that of bellows. The one-piece joints are made in all sizes with standard flanges for either high-pressure or low-pressure pipe lines. The high-pressure joints are designed to allow an expansion and contraction of 1 in. (2.5 cm.) from normal, or a total movement of 2 in. (5 cm.). The low-pressure joints allow 0.31 in. (0.8 cm.) movement over or under normal, or a total movement of 0.63 in. (1.6 cm.). Limiting bolts are provided as shown to prevent expansion beyond the safe limit, and a sliding sleeve is also inserted in the high-pressure joints to minimize friction and help support the internal pressure strain.

Trade Notes

THE H. W. JOHNS-MANVILLE COMPANY'S Youngstown (Ohio) office is now at 520 Market Street.

THE VARNALL-WARING COMPANY of Philadelphia has decided to group its several products under the name of "Yarway."

THE HOMESTEAD VALVE MANUFACTURING COMPANY of Homestead, Pa., has opened a branch office at 1 Franklin Street, New York City.

THE CLEMENS ELECTRICAL CORPORATION, 725 Main Street, Buffalo, N. Y., has appointed the Doherty-Hafner Company, 618-626 West Jackson Boulevard, Chicago, its agent.

ROBERT S. BLAKE, formerly employed by the Conduit Electric Manufacturing Company of Boston, Mass., in charge of the Philadelphia office, has been made district manager in the Chicago territory for the Duquesne Electric & Manufacturing Company. Mr. Blake has headquarters at 230 South La Salle Street, Chicago.

THE HOTPOINT DIVISION OF THE EDISON ELECTRIC APPLIANCE COMPANY, INC., of Chicago, New York and Ontario, Cal., has formulated extensive publicity plans to increase the use of electrical appliances. The Hotpoint distributors have been sent a complete outline of promotion plans for the first half of 1918.

A. D. ALEXANDER has purchased the Pittsburgh office of the Richard D. Kimball Company, consulting engineer, and will continue the business under his own name. Mr. Alexander has been resident engineer in charge of the Pittsburgh office of the above concern for the past three years and was formerly engineer with the Pittsburgh Board of Public Education.

THE NAVY DEPARTMENT, Bureau of Supplies and Accounts, division of inland traffic, has issued, under date of March 21, a set of instructions to navy contractors concerning car supply and expeditious trade movement—carload and less than carload. A copy of these instructions can be had from H. P. Anewald, manager inland traffic, Navy Department, Washington, D. C.

MACGOVERN & COMPANY of New York City, well-known dealers in second-hand equipment, announce the opening of branch offices at Pittsburgh, Pa., and St. Louis, Mo. The office in Pittsburgh is at 498 Union Arcade and is under the direction of L. H. Tippins and W. L. Sprengle. The St. Louis office is at 315 North Twelfth Street and is under the direction of R. S. Fisher, district manager.

WILLIAM C. MAGELSEN, United States Consul, advises the Bureau of Foreign and Domestic Commerce that Melbourne, Australia, has a movement now on foot to secure the standardization of all electrical goods. When standards have been adopted the schedules will be made available by the Commonwealth Bureau of Science and Industry, and copies will be very serviceable to American manufacturers intending to compete in this trade.

THE SPRAGUE ELECTRIC WORKS OF THE GENERAL ELECTRIC COMPANY are now in the new building in Bloomfield, N. J., which provides increased capacity for the manufacture of generators, motors and controllers, dynamometers, hoists, ozonators and electric fans. It is of reinforced concrete, 75 ft. by 550 ft., with an L 75 ft. by 175 ft., six stories in height, walls and columns being designed for the addition of another story should it be necessary at some future time.

W. H. HOLCOMB has joined the sales forces of the Moloney Electric Company and will be connected with the home office in St. Louis. Formerly Mr. Holcomb was sales engineer for the Frank Adam Electric Company of St. Louis, and later he was with the Allis-Chalmers Company of Milwaukee. More recently he had returned again to the employ of the Frank Adam Electric Company and had been opening branch offices for that concern at Detroit, Cincinnati, Minneapolis and Washington, D. C.

THE IRVINGTON (N. J.) VARNISH & INSULATOR COMPANY has made plans for giving free to each employee who has been drafted or who has enlisted a life insurance policy for \$2,500, the premiums to be paid by the company during the period of the war. There are at present about 460 employees who will benefit by this action. If other employees are drafted or enlist, they will automatically come within the provisions of this gift. This was done by the company in its desire to

make sure that any dependents of its soldier employees should not be left destitute in any circumstances.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY has just announced that, as of April 1, 1918, the Copeman Electric Stove Company will be merged in a new company to be known as the Westinghouse Electric Products Company, with headquarters and factory at Mansfield, Ohio. This factory will be devoted to the manufacture of heating appliances previously made at the Newark works of the Electric Company and the Flint (Mich.) works of the Copeman Electric Stove Company. The general operations of the Westinghouse Electric Products Company will be directed by W. K. Dunlap as general manager. Mr. Dunlap is also assistant to vice-president of the Westinghouse Electric & Manufacturing Company.

THE WAR TRADE BOARD, Washington, D. C., under date of March 28, addresses the following notice to exporters and importers: "It has come to the attention of the War Trade Board that various individuals, firms and corporations have been advertising their services to be rendered in the matter of securing export and import licenses. The War Trade Board suggests that it is not necessary for exporters and importers to consult such agencies. The various bureaus of the War Trade Board will supply all the information desired on receipt of requests therefor. The board desires to place as little inconvenience and expense upon importers and exporters as possible, and therefore this suggestion is made in order that they may not be put to the expense of employing such agencies to obtain licenses unless they so desire."

Trade Publications

PUMPS.—The Manistee Iron Works Company, Manistee, Mich., has issued a catalog entitled "The Pump That 'Manistee' Builds." An exploded view brings out the features of the pump construction. Data on operating characteristics are given.

DISCONNECTING HANGERS.—"Do Your Reflectors Reflect?" is the title of a circular being circulated by the Thompson Electric Company, 5606 Euclid Avenue, Cleveland, which illustrates the principle of the Thompson "safety" disconnecting hangers. These hangers allow the reflectors to be cleaned easily.

LAVA INSULATORS.—The Tennessee Burner Manufacturing Company of Chattanooga, Tenn., has issued a circular entitled "After Your Patronage," describing its lava insulators for high-frequency circuits. These insulators are designed to withstand a temperature of more than 2000 deg. C. and are made in any shape or form.

HYDROELECTRIC TURBINES.—The Allis-Chalmers Manufacturing Company, Milwaukee, Wis., has issued a circular illustrating the most powerful high-head turbine in the world. The turbine, which is used by the Puget Sound Traction, Light & Power Company, is rated at 25,000 hp. and rotates at 360 r.p.m. against a 440-ft. (134-m.) head.

INDUSTRIAL POWER-PLANT CONSTRUCTION.—The Guarantee Construction Company, 140 Cedar Street, New York, is distributing bulletin No. 122, entitled "Economic Handling and Storage of Coal, Ashes and Other Material." The bulletin is well illustrated and shows actual installations that the company has designed and constructed. A description of the Darley suction conveyor is given and its advantages are pointed out.

STEAM TABLES FOR CONDENSER WORK.—The Wheeler Condenser & Engineering Company, Carteret, N. J., has issued the fourth edition of a bulletin entitled "Steam Tables for Condenser Work," which is a handbook of steam tables with pressures below atmosphere expressed in inches of mercury referred to a 30-in. (762-mm.) barometer. It also includes discussions on the use of the mercury column and the accuracy of such measurements.

INDUSTRIAL TRUCKS CHARGING OUTFIT.—A folder has just been issued by the Cutler-Hammer Manufacturing Company of Milwaukee, illustrating and describing the "C-H" sectional battery-charging equipment for industrial electric trucks. A type of battery-charging outfit is referred to which is especially suitable for public and private garages. This charging equipment is provided in sections, each of which is a complete charging unit so that new sections can be added with the purchase of additional trucks.

SILK TAPE.—The Mitchell-Iland Manufacturing Company, 99 John Street, New York, is distributing a card price list of its plain silk insulating tapes. A sample of silk tape is attached to the card and prompt delivery is assured.

BOILER METERS.—"How to Save Coal" is the title of a circular being distributed by the Bailey Meter Company of 141 Milk Street, Boston. The bulletin shows the things that must be considered in the boiler room to obtain efficient operation.

ELECTRICAL EQUIPMENT IN THE WOODWORKING INDUSTRY.—This is the title of circular 7133, being distributed by the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa. The bulletin describes the applications of electric drive in woodworking industry and shows actual installations. Motors and their controllers are very clearly described in the bulletin. In the back of the booklet is a table giving the power requirements of woodworking machinery. Practically every machine used in the woodworking industry is listed in the table.

New Incorporations

THE MEASURED SERVICE METER COMPANY of Uniontown, Pa., has been incorporated by R. A. Neville and others. The company is capitalized at \$50,000 and will make telephone and other meters.

THE CEILITE COMPANY of Utica, N. Y., has been incorporated with a capital stock of \$100,000 by W. L. Foley, W. I. Taber and S. Garfunkel of Utica. The company proposes to manufacture gas and electric fixtures.

THE ELECTRIC ZINC RUST PROOF COMPANY of Detroit, Mich., has been chartered with a capital stock of \$10,000 to deal in solution and electroplating equipment. The incorporators are: Alfred T. Warner, Charles G. Bennett, Thompson W. Kirby.

THE HOME LIGHTING & STORAGE BATTERY COMPANY of Newcastle, Ind., has been incorporated by Samuel N. Denton, Luther O. Draper and Isaac E. Hays. The company is capitalized at \$25,000 and proposes to manufacture storage batteries.

THE LIBERTY LIGHTING SUPPLY COMPANY of New York, N. Y., has been incorporated by M. P. Hartman, A. Weiss and H. Hoffman, 2270 Seventh Avenue, New York. The company is capitalized at \$5,000 and proposes to manufacture lighting fixtures.

THE AMERICAN ELECTRIC PRODUCTS COMPANY of Montreal, Que., has been incorporated by L. Macfarlane, W. B. Scott, J. McNaughton and others. The company is capitalized at \$1,500,000 and proposes to manufacture electrical equipment, machinery, etc.

THE CELL BEAM CORPORATION of New York, N. Y., has been incorporated with a capital stock of \$5,000 to manufacture and deal in lighting fixtures. The incorporators are: J. Record, R. W. Wadman and N. G. Rost, 251 West Ninety-eighth Street, New York, N. Y.

THE JONAS LALLEY LIGHT COMPANY of Milwaukee, Wis., has been incorporated by August A. Jonas, John P. Peterson and Gustave Jonas. The company is capitalized at \$25,000 and proposes to manufacture and install electric-lighting systems in isolated localities.

THE AUBURN ELECTRICAL COMPANY of Androscoggin, Auburn, N. Y., has been incorporated with a capital stock of \$10,000 to do a general electrical and automobile business. The officers are: Fred H. Lancaster, president, and Elmer W. Nickerson, treasurer and clerk.

THE AMERICAN FUEL SAVING ENGINEERING CORPORATION of Fort Wayne, Ind., has been chartered with a capital stock of \$1,000,000 by Austin W. Stultz, Charles H. Hall and Bruce M. Wylie. The company proposes to manufacture fuel-saving and smoke-consuming devices.

THE GEORGE POEHLMANN & SON COMPANY, 430 Third Street, Milwaukee, Wis., has been chartered with a capital stock of \$50,000 to take over the business of George Pöehlmann & Son, manufacturers of industrial electrical generating and distributing equipment. Orville G. Pöehlmann is secretary and treasurer.

THE SUN POWER EQUIPMENT COMPANY has filed articles of incorporation under the laws of the State of Delaware with a capital stock of \$10,000. The company proposes to do an electrical engineering business, etc. The incorporators are: C. L. Rimlinger, M. M. Clancy and F. A. Armstrong, Wilmington, Del.

New England States

BANGOR, ME.—The Eastern Maine Railroad Company, it is reported, contemplates the construction of either a steam or electric railway from Bangor, crossing the Penobscot River to Brewer, thence in an easterly direction through the timberlands of eastern Maine through Holton, a distance of 112 miles. Right-of-way has been purchased for about 32 miles.

CONCORD, N. H.—Extensive improvements are under consideration by the Boston & Maine Railroad Company at its local plant, which provide for the erection of a new roundhouse and other changes. As yet nothing definite has been decided upon.

BRANDON, VT.—The Public Service Commission has granted the petition of the Fortonia Power Company asking permission to make a contract with Wetherbee & Sherman, owners of the Iron mines and other industries, in Port Henry, N. Y., whereby the company might borrow \$75,000 for development work. The project upon which the loan is to be expended is situated short distance south of Middlebury.

BOSTON, MASS.—Plans have been filed by the New York, New Haven & Hartford Railroad Company for the construction of a one-story electric battery building, about 100 ft. by 140 ft., at Dover, near Boston. Contract has been awarded to C. W. Murock, 185 Church Street, New Haven, Conn.

CLINTON, MASS.—A 66,000-volt transmission line, 16 miles long, connecting the power station at the Wachusett dam in Clinton with the power station at the Sudbury basin in Southboro will be completed about May 1. An existing electric transmission line, 1415 ft. long, connects the Wachusett station with the New England Power Company's line and a 13,200-volt transmission line connects the Sudbury power station with the line of the Edison Electric Illuminating Company. William E. Ross, 1 Ashburton Place, Boston, is chief engineer of the Metropolitan Water and Sewerage Board.

SHIRLEY, MASS.—The Shirley Electric Company has purchased the G. M. Ballou mill property, including a valuable water power, located in the center of the village. The company, it is understood, contemplates the construction of a new electric generating plant, together with substations.

SPRINGFIELD, MASS.—Contract has been awarded by the United Electric Illuminating Company for improvements to its State Street plant to the Stone & Webster Engineering Corporation of Boston. The cost of the work is estimated at about \$300,000 and the plans provide for the installation of entire new switching equipment throughout the plant to replace the apparatus now in use, and a 25,000-hp. steam turbine to take the place of 16 of the old 400-hp. boilers.

SPRINGFIELD, MASS.—Work has been started by the Turners Falls Power & Electric Company on the construction of towers across Hampton Plains to the Springfield Street Railway Company's station on the Westfield River dike preparatory to erecting wires from the Southampton town line. The power belt will continue down the dike to East Main Street crossing the highway in the vicinity of Little River Street and hence to the Agawam town line.

WEST STOCKBRIDGE, MASS.—The local electric-light plant, owned by J. F. Bossidy, has been purchased by the C. D. Parker Company of Boston.

WHITMAN, MASS.—The town has voted to enter into a new five-year contract with the Edison Electric Illuminating Company of Brockton for lighting the streets of the town, under the terms of which ornamental lamps will be erected in the business district of the town.

NARRAGANSETT PIER, R. I.—The Town Council has agreed to accept the proposal of the Narragansett Pier Electric Light & Power Company for changing the lighting system on Caswell Street and placing the wires underground, provided the town will pay one-third of the cost.

BRIDGEPORT, CONN.—Plans of the United Illuminating Company of Bridgeport for the erection of a three-conductor 6600-volt transmission line on jointly used poles have been approved by the Public Utilities Commission, because "of the emergency due to war conditions."

Construction

News of Projects, Plans, Bids and Contracts. Notes on Work Under Way

ALBANY, N. Y.—The Public Service Commission has authorized the Hudson Power Corporation to issue \$15,000 in capital stock. The company was incorporated to build a power plant on the Wallkill River near Rifton.

AUBURN, N. Y.—Application has been filed by the Empire Gas & Electric Company and the Empire Coke Company for authority to issue \$170,000 in joint bonds, the proceeds to be used for extensions and new equipment in both the gas and electric departments, including new transmission lines. The principal work is to be a new substation on Clark Street to supply electricity to the manufacturing plants in the city.

BROOKLYN, N. Y.—Plans have been prepared by G. L. Knight, 13 Willoughby Street, for alterations and improvements to the power house of the Edison Electric Company on Gold Street.

BROOKLYN, N. Y.—The Bureau of Yards and Docks, Navy Department, Washington, D. C., has awarded contract to Westinghouse, Church, Kerr & Company for the construction of a one-story power house, 45 ft. by 80 ft., at the Brooklyn navy yard.

BROOKLYN, N. Y.—The War Department has decided to take over the waterfront property between Fifty-seventh and Sixtieth Streets at Bay Ridge, Brooklyn, on which it will erect a permanent quartermaster's warehouse, at a cost of about \$25,000,000.

NEW YORK, N. Y.—Plans are under consideration by the Edison Storage Battery Company for the erection of a new three-story building, about 60 ft. by 100 ft., at 247-51 West Thirty-fifth Street.

NEW YORK, N. Y.—Bids will be received by the board of trustees or the curator of the College of the City of New York, 114 Main Building, 139th Street and Convent Avenue, New York, until April 16, for alterations and repairs, including the installation of electric-lighting system and alterations to fire-alarm system in the basement of the first story west of the main stair hall in the Twenty-third Street building of the College of the City of New York, Lexington Avenue and Twenty-third Street. Copies of specifications, etc., may be obtained at the office of Crow, Lewis and Wickenhoefer, architects, 200 Fifth Avenue.

NYACK, N. Y.—The capital stock of the Rockland Light & Power Company has been increased from \$1,000,000 to \$1,300,000.

OXFORD, N. Y.—Bids will be received by Mrs. Georgianna Griffith, president of the board of managers of the New York State Women's Relief Corps Home, Oxford, until April 24 for a refrigeration plant. Drawings and specifications may be obtained from the New York State Women's Relief Corps Home, Oxford, at the New York City office of the Department of Architecture, Room 1224 Woolworth Building, and at the Department of Architecture, Capitol, Albany.

ST. GEORGE, S. I., N. Y.—Bids will be received by the president of the borough of Richmond, Borough Hall, St. George, New Brighton, until April 18, as follows: (1) For lighting fixtures of an additional county court house in the county of Richmond located at Jay and De Kalb Streets and Stuyvesant Place, St. George, contract No. 10: (a) For the entire work, complete, using brass plated steel chain for hanging fixtures; (b) for the entire work, using solid brass chain for hanging fixtures. (2) For electric clocks for the above court house. Blank forms, plans and specifications may be obtained at the office of the engineer, Bureau of Engineering, Borough Hall, St. George.

UTICA, N. Y.—The capital stock of the J. & M. Electric Company has been increased from \$25,000 to \$50,000.

WATERVILLE, N. Y.—Application has been filed with the Public Service Commission by the Waterville Gas & Electric Company for permission to construct and operate an electric distribution system to supply electricity for lamps and motors in the town of Marshall under a franchise granted by the Town Board in February.

BORDENTOWN, N. J.—Plans are being considered by the Board of Commissioners for the installation of new electric-lighting fixtures throughout the city hall building in connection with other improvements.

KEARNEY, N. J.—Plans are being prepared by the Niles-Bement-Pond Company,

111 Broadway, New York, N. Y., for the construction of new plant on the Lincoln Highway and the Hackensack River, Kearney. The cost of the initial work is estimated at about \$2,000,000, and the plant will specialize in the manufacture of industrial locomotives and heavy machinery. Harris & Richards, Drexel Building, Philadelphia, Pa., are the architects.

NEWARK, N. J.—Plans have been filed by the New York Telephone Company, 15 Dey Street, New York, for improvements and alterations to its local telephone exchange building. Contract has been awarded to W. A. L'Hommiedieu, 1 Madison Avenue, New York City.

TRENTON, N. J.—Plans are being prepared by the Crescent Insulated Wire & Cable Company, Olden and Taylor Streets, for the erection of a three-story addition, about 85 ft. by 100 ft., to its factory. The company manufactures cables, electric wire, etc.

BRIDGESBURG, PA.—The Henry A. Hitter's Sons Company, Gaul and Hazzard Streets, Philadelphia, manufacturer of hardware and iron and steel specialties, contemplates the construction of a new plant at Buckius and Lefevre Streets, Briddlesburg. Three buildings will be erected, one 110 ft. by 500 ft., two stories, and two shops, each 80 ft. by 150 ft., one story high.

CLIFTON HEIGHTS, PA.—Contract has been awarded by the Kent Manufacturing Company for the construction of its proposed power house to D. J. McNamee of Philadelphia, Pa.

EAST BRADFORD, PA.—Contract has been awarded by the Kendall Refining Company for the construction of an addition to its boiler plant, about 40 ft. by 75 ft.

KITTANNING, PA.—The Triple Airless Tire Company of Pittsburgh is planning to build a new plant in Kittanning, to cost about \$85,000. The plans provide for the erection of a power plant, about 40 ft. by 80 ft. Herbert & Henderson of Kittanning are architects.

NEWCASTLE, PA.—The contract for the installation of a curb lighting system in the Seventh Ward has been awarded to the Ochiltree Electric Company of Pittsburgh, at \$14,149.

PARKESBURG, PA.—Plans have been filed by the Parkesburg Iron Company for the erection of an addition to the boiler plant at its works. Contract has been awarded to the Rust Engineering Company, Penn Building, Philadelphia.

PHILADELPHIA, PA.—Permit has been taken out by the Bell Telephone Company for the construction of a new building at 5154 Lancaster Avenue.

PHILADELPHIA, PA.—The Philadelphia Storage Battery Company, Ontario and C Streets, is contemplating the construction of an addition, 40 ft. by 100 ft., one story, to its plant.

PHILADELPHIA, PA.—Work will soon begin by the Philadelphia Rapid Transit Company on the extension of its railway on Island Avenue at Eastwick to the ship-building works of the American International Company at Hog Island.

PHILADELPHIA, PA.—The Atlantic Refining Company, 3144 Passyunk Avenue, has awarded contract to Metzger & Fisher, Otis Building, for improvements and alterations to its power house at Thirteenth and Race Streets, to cost about \$11,300.

PHILADELPHIA, PA.—Contract has been awarded by the Electric Service Supplies Company, Seventeenth and Cambria Streets, to the John N. Gill Company, Otis Building, for improvements to its plant. The company manufactures electrical supplies, etc.

PHILADELPHIA, PA.—Plans have been filed and contract awarded by the Philadelphia Storage Battery Company, Ontario and C Streets, for the construction of an addition to its plant, about 40 ft. by 100 ft. Contract has been awarded to Stewart Brothers, 2526 Orkney Street, Philadelphia, Pa.

REYNOLDS, PA.—The Atlas Powder Company has awarded a contract for the construction of power house and large outside buildings at Reynolds to Andrew Breslin of Summit Hill.

SHAMOKIN, PA.—The Pennsylvania Lighting Company, which supplies electricity in both Shamokin and Mount Carmel, together with a number of other towns in this vicinity, contemplates the erection of an electric transmission line to Natalie this summer.

FORT DUPONT, DEL.—Plans have been prepared for the erection of a one-story radio station at Fort Dupont for the United States government.

Middle Atlantic States

ALBANY, N. Y.—Notice has been filed with the Secretary of State by the Havens Electric Company of an increase in capital stock from \$25,000 to \$100,000. Morton Havens, Jr., is interested in the company.

BALTIMORE, MD.—The Consolidated Gas, Electric Light & Power Company has awarded contract for construction of a substation to the Cogswell-Koether Company. The proposed building will be 26 ft. by 40 ft. one story high.

BALTIMORE, MD.—S. W. Greenland, general manager of the Port Wayne & Northern Indiana Traction Company, has been engaged by the United States government to supervise the construction of a government power plant at Baltimore.

BALTIMORE, MD.—Plans are being considered by the City Council for extending the electric lighting, fire prevention, sewerage, etc., to the four new wards recently annexed to the city. Immediate attention will be given to lighting the roadways. Special attention will probably be given to such suburbs as Roland Park and Mount Washington in regard to lighting the streets, and the system throughout Highlandtown and Canton and other industrial suburbs will be greatly improved.

MOUNT AIRY, MD.—The Mount Airy Ice & Electric Company is contemplating the installation of an additional generating unit and establishing a day service. C. C. Riddemoser is manager.

MYERSVILLE, MD.—The City Council is considering the question of establishing a municipal electric-light plant and water-works system.

CHARLESTON, W. VA.—The Charleston-Dunbar Traction Company, it is reported, contemplates placing contracts in the near future for the construction of a new power house and for two new boilers.

CHARLESTON, W. VA.—Plans are being prepared by the Charleston Interurban Railway Company for improvements to its system, involving an expenditure of about \$500,000 among which is included the construction of a 2-mile extension.

OLCOTT, W. VA.—The Kanawha Central Power Company, recently incorporated, is planning to construct and operate an electric power plant. The company is capitalized at \$100,000. I. C. Jordan and S. B. Avis are interested in the company.

NORFOLK, VA.—The Norfolk & Western Railroad Company is contemplating extensions to its shops and yards at North Bristol, involving an expenditure of about \$300,000.

WASHINGTON, D. C.—The Washington-Virginia Railway Company is considering an extension of its system from Mount Vernon to Camp Humphrey, a distance of 4 miles.

North Central States

CHARLEVOIX, MICH.—The city of Charlevoix has recently placed a contract for a 300-hp. Leffel water wheel and generator to be installed at Bellaire, to be in operation by July 1. In the issue of Feb. 9 an item was published stating that the city of Charlevoix has leased the plant of the Hydraulic Power & Light Company of Bellaire. Through mistake the present equipment of the plant was given as new equipment contemplated for the plant. The transmission line (28 miles) was erected in 1906. A. J. Hamilton is superintendent.

FRANKFORT, MICH.—Bonds to the amount of \$5,000 have been voted for improvements to the water-works system. It is proposed to replace the engines in the pumping station with electric motors.

CANTON, OHIO.—Improvement and alterations in the local system of the Ohio State Telephone Company, involving an expenditure of about \$200,000, have been authorized by the State Public Utilities Commission.

CLEVELAND, OHIO.—The Cleveland Electric Illuminating Company is planning to erect a two-story addition, 35 ft. by 165 ft., to its switch house. New equipment, including electric switches, generators, etc., will be purchased. F. Hansel, 408 Illuminating Building, is architect.

HICKSVILLE, OHIO.—Steps have been taken to secure the installation of a new lighting system in Hicksville.

MARIETTA, OHIO.—Application will be made to the City Council by the Kanawha Traction & Electric Company for a new franchise. The company contemplates a number of improvements in its system and service. The present franchise of the company expires in about three years.

MASSILLON, OHIO.—The plant of the Massillon Electric & Gas Company was recently damaged by fire, causing a loss of about \$30,000.

SANDUSKY, OHIO.—The contract for electrical apparatus and fixtures for the new Good Samaritan Hospital Building has been awarded to Bonn Electric Company, at about \$10,000.

YOUNGSTOWN, OHIO.—Work will begin at once by the Mahoning & Shenango Railway & Light Company on the erection of an electric transmission line from Lowellville to McDonald. This line will supply energy to operate the Youngstown & Niles Railway, now under construction.

HARLAN, KY.—Work has begun by the United States Coal & Coke Company on the development of 30 acres of coal land in Harlan County. The company, which is a subsidiary of the United States Steel Corporation, contemplates an expenditure of \$4,000,000 with the expectation of ultimately producing from 10,000 to 12,000 tons per day. A modern town is being erected to accommodate 6000 workmen and their families.

LOUISVILLE, KY.—The Home Electric Company of Louisville has secured the contract for wiring the 29 new buildings at the quartermaster's depot at Jeffersonville; also the 15 new buildings to be erected by the Aetna Powder Company, near the Kentucky State Fair Grounds.

GOSHEN, IND.—The Hawks Electric Company is contemplating extending its electric transmission line from the Cope land farm, north of Ligonier, through that city to Cromwell, where it has a lighting contract. Electrical service will also be furnished to the farmers along the line.

CHICAGO, ILL.—The property at Prairie Avenue and Twenty-fourth Street has been purchased by the Packard Motor Company, which, it is understood, will erect a six-story service station for passenger cars and trucks. The cost of building and site is estimated at about \$800,000.

EAST ST. LOUIS ILL.—The capital stock of the East St. Louis Light & Power Company has been increased from \$1,100,000 to \$1,200,000.

OAKLAWN, ILL.—Preparations are being made by the Chicago & Eastern Illinois Railroad Company for the construction of an addition to its power house at Oaklawn to provide space for a large Ide generator to be installed. Contract has been placed for generator.

PERRY, ILL.—The Perry Light & Power Company has filed a petition with the Illinois Public Utilities Commission asking permission to discontinue business on the ground that the plant is not making expenses.

SPRINGFIELD, ILL.—The Springfield Plow Company is planning to build a new warehouse four stories, complete with lighting apparatus and sprinkler system, to cost about \$35,000.

ASHLAND, WIS.—The Ashland Light, Power & Street Railway Company is planning to build a new hydroelectric plant at Superior Falls, to cost about \$100,000. The L. E. Meyers Company, 58 West Jackson Boulevard, Chicago, Ill., engineer and contractor, has charge of the work.

MILWAUKEE, WIS.—Plans are being considered by the Pelton Steel Company, Elliott Place and Chicago Road, for further extensions to its plant, which is equipped with a large electric furnace unit. The plans provide for the erection of two new buildings, to be equipped with an electrically-operated traveling crane and other machinery. As yet nothing definite has been decided upon. T. H. Harvey is general manager.

PESHTIGO, WIS.—The local electric-light plant is reported to have been purchased by T. A. Pamerin. Improvements are contemplated, it is understood, including the construction of a new dam and the purchase of additional equipment.

PLATTEVILLE, WIS.—Arrangements have been made between the Interstate Light & Power Company of Platteville and the Mineral Point (Wis.) Service Company to connect their transmission lines from Rewey to Platteville to provide emergency service to the mines at Rewey. In case the energy cannot be supplied from the Mineral Springs plant, it can be obtained from Galena.

SUPERIOR, WIS.—The Lake Superior Electrical Company of Superior has been reorganized under the name of the Benson Electric Company and the capital stock increased from \$50,000 to \$250,000. The company manufactures automatic electric signals and steering control systems. M. B. Benson is president.

MANKATO, MINN.—A committee has been appointed to look into the question of establishing a municipal electric-lighting plant in Mankato.

EDDYVILLE, IOWA.—At an election held recently the proposal to issue \$8,000 in bonds for improvements to the municipal electric light plant was carried.

HUMBOLDT, IOWA.—Bids will be received by the board of education of Humboldt until April 26 for the construction of a high school building, including steam

heating, electric wiring, vacuum cleaner, temperature regulator, etc. The cost of the building is estimated at \$110,000. J. E. Barker is secretary of board.

OTTERVILLE, MO.—The installation of an electric-light plant in Otterville is reported to be under consideration. Jesse Starren is interested.

BOWMAN, N. D.—The purchase of the electric plant of the Bowman Electric Light & Power Company is reported to be under consideration by Fred Cole of Broadhead, Wis., and Frank Christopher of Albany, Wis. If the deal goes through, it is understood that a new plant will be installed.

DALTON, NEB.—Bids will be received by the village of Dalton until April 30 for the construction of a power plant building, 36 ft. by 40 ft. Plans and specifications may be obtained at the office of Royal D. Salisbury, consulting engineer, 1415 East Colfax Avenue, Denver, Col., upon deposit of \$10.00.

OGALALLA, NEB.—The installation of a 5-kw. series street-lighting circuit is under consideration by the Council. James H. Class is superintendent of the municipal electric-light plant.

OMAHA, NEB.—Revised plans have been completed by the Metropolitan Water District for the construction of an ice plant on Twentieth Street and Poppleton Avenue, to cost about \$24,000. Bids will be taken on insulation, cooler doors, electric wiring, etc. R. B. Howell is general manager.

SIDNEY, NEB.—The contract for improvements to the municipal electric-light plant and water-works system has been awarded to the O'Fallen Supply Company of Denver, Col., at \$30,592.

DIGHTON, KAN.—Bonds to the amount of \$15,000 have been voted for improvements to the municipal electric-light plant and waterworks system.

LIBERAL, KAN.—The installation of a new street-lighting system in Liberal is reported under consideration. It is proposed to use ornamental standards carrying cluster lamps.

MORLAND, KAN.—The City Council is considering the installation of an oil engine and generator soon. F. S. Kay is superintendent of the municipal electric-light plant.

NORTH MANHATTAN, KAN.—Bids will be received by George W. Titus, president of the Rebekah Oddfellows' Home, Eureka, care of William J. Russell, Grand Secretary, Topeka, Kan., until April 29 for the construction of the Rebekah Oddfellows' Home at Eureka Lake. Separate bids to be submitted for heating apparatus, kitchen equipment, laundry machinery and refrigerator.

ROSSVILLE, KAN.—Preparations are being made by the Rossville Electric Light & Power Company to enlarge its plant and add steam power. The company is arranging to extend its transmission lines to Delia, Silver Lake and Willard. J. W. Phares is president.

Southern States

CHARLOTTE, N. C.—The Southern Public Utilities Company is contemplating increasing the generating capacity of its plant.

CHARLOTTE, N. C.—The Charlotte Electric Repair Company has awarded contract for a new addition to its plant, to cost about \$5,000.

MORGANTOWN, N. C.—The Southern Power Company, it is reported, is considering the construction of a hydroelectric plant on the Johns River.

PINE LEVEL, N. C.—The Citizens' Power Company is planning the erection of two new substations in connection with its proposed 13-mile transmission system, which will connect several towns.

REIDSVILLE, N. C.—Bonds to the amount of \$10,000 have been voted for extensions and improvements to the municipal electric-light plant.

CHARLESTON, S. C.—The Charleston Consolidated Railway & Lighting Company is now building a 500-kw. rotary substation near the navy yard to supply direct current to the suburban railway. J. D. Felton is chief engineer.

COLUMBIA, S. C.—Work has begun on the enlargement of the Omussee plant of the Columbia Power Company, to cost about \$500,000. The company, it is reported, is contemplating establishing a plant at Kelson, to cost approximately \$500,000. Tucker & Laxton of Charlotte, N. C., have charge of the work at the Omussee plant. Through error this item was published under Columbia, Ala., in the issue of March 30.

SUMTER, S. C.—The installation of a municipal electric-light plant is reported to be under consideration by the City Council.

ATLANTA, GA.—Bids will be received by the Department of Justice, office of superintendent of Prisons, Washington, D. C., until April 16, for furnishing electrical equipment at the United States Penitentiary, Atlanta, including a switchboard, power panel and electric feeders for lamps and motors in east main cell wing. Copies of specifications may be obtained on application to the above office.

COMMERCE, GA.—The City Council is considering calling an election to vote on a proposal to issue \$15,000 electric light bonds.

JEFFERSONVILLE, GA.—Bonds to the amount of \$21,000 have been authorized of which the proceeds of \$6,000 will be used for the installation of a municipal electric-light plant and the remainder for water-works system.

SAVANNAH, GA.—Application will be made for a charter for the Chatham County Traction Company for the purpose of constructing an electric railway from the intersection of Augusta Avenue with Lathrop Avenue, Savannah, to Port Wentworth, a distance of about 6 miles. The company so proposes to own and operate an electric plant and to supply electricity for lamps and motors. The company is capitalized at \$50,000. The incorporators are: H. C. Ross, secretary of the Savannah Electric Company; W. W. Osborne, A. A. Lawrence, David S. Atkinson and Edmund H. Abrahams, all of Savannah.

MOBILE, ALA.—The Murnan Shipbuilding Company has purchased a tract on the east shore of Mobile River, to be utilized for extensions to its shipyards, which will include the erection of a shed and sawmill with a daily capacity of 50,000 ft. of lumber, extensions to electric-lighting plant, dredge and fill.

RUSSELLVILLE, ARK.—The Arkansas Light & Power Company is installing a 1000-hp. steam turbine and a 1500-kw. generator (directly connected) in its Russellville plant. This is supplementary to the present 750-kw. generating unit and the large turbines and generators at the dam.

BLACKWELL, OKLA.—At an election held recently bonds to the amount of \$82,000 were voted, the proceeds to be used for improvements to extensions to the municipal electric-light plant and system; also \$75,000 for waterworks, and \$15,000 for fire-fighting apparatus.

PRAGUE, OKLA.—At an election held recently the proposal to issue \$30,000 in bonds, the proceeds to be used for improvements to the municipal electric-light plant and water-works system, was carried.

DALLAS, TEX.—The Dallas Electric Light & Power Company has submitted to F. N. Baker, supervisor of public utilities, for approval requisitions amounting to \$2,800,000. Nine of these requisitions, which it is estimated will cost \$797,713, have been approved, among which are included the erection of a high-tension transmission line connecting the power house of the Texas Electric Power & Light Company at Norwood for exchange of power in case of breakdowns, also for changes in the generating plant and improvements to the distribution system; this work is under way. Requisition No. 3 is for the construction of a new substation in Oak Cliff and connecting the substation with main power station and the downtown substation; No. 11 is for the erection of an electric transmission line to Love Field, to cost \$16,329.

Pacific and Mountain States

BREMERTON, WASH.—Bids will be received at the Bureau of Yards and Docks, Navy Department, Washington, D. C., until April 15, under specification 2908 for an electric traveling crane for the gun shop building No. 140, naval station, Puget Sound, Wash. Further information may be obtained from the chief of the above bureau.

HOQUIAM, WASH.—A new machine shop and foundry, each 80 ft. by 140 ft., are being erected by the Lamb Machine Works. An electric steel furnace will also be installed.

SEATTLE, WASH.—The Acme Electric Company of Seattle has been awarded contract for installing electric fixtures, etc., in the offices of the United States Steel Products Company.

SEATTLE, WASH.—The Pacific States Electric Company, 570 First Avenue, South, Seattle, Wash., has been awarded contract

by the Sloan shipyards of Olympia for electrical supplies in the twenty 3500-ton wooden ships now being built by the company.

SEATTLE, WASH.—Beginning with April all cluster lamps in the downtown district, with the exception of four at each corner of street intersections, have been eliminated. If the experiment proves feasible the plan will be continued. The action was taken for the purpose of conserving oil, for which the city is spending \$800 per day. It is estimated that by eliminating the cluster lamps between street intersections \$30,000 a year can be saved. No change will be made in the residence districts.

SEATTLE, WASH.—The lowest bid received by the Board of Public Works for the construction of a hydroelectric plant on the Skagit River was submitted by Grant Smith & Company, at \$2,381,000, on plans prepared by the firm's engineers; on plans and specifications prepared by the city the company's bid was \$4,297,000, both bids calling for cash rather than utility bonds. No bid was submitted for a transmission line, the cost of which is estimated at \$1,000,000, or for a substation within the city limits. The same firm submitted a bid of \$3,556,000 for a completed power plant on Wallace River, one of the tributaries of the Sykomish River, near the town of Gold Bar. Two bids were submitted by the Packwood Lake Construction Company for a completed power plant on Packwood Lake, at \$4,031,000 for high-tension switching outside, and \$4,121,000 for a complete power plant with switching inside. The Puget Sound Bridge & Dredging Company offered to develop the Skagit River project, together with transmission line and city substation, at cost of construction plus 15 per cent, and to accept payment in utility bonds. The same company offered a completed power plant on the Stillaguamish River project, offered to the city some time ago by J. C. Eden, owner, for \$4,200,000 for steel penstock and \$4,100,000 for wood penstock construction. The bids on a completed plant on the Skagit River cover the initial development on a project that may ultimately be increased to from 300,000 kw. to 500,000 kw.

WAPATO, WASH.—The City Council is considering a contract with the Pacific Power & Light Company for a new lighting system for the city, which will include new lamps for the business district and a number of 100-cp. lamps in the residence section suspended on brackets.

BAKER, ORE.—The Cornucopia Mines Company of Baker has recently been granted permission to appropriate the waters of Elk, Jim Fiske and Fall Creeks for power development.

KLAMATH FALLS, ORE.—Arrangements have been made between the California-Oregon Power Company and the Pacific Gas & Electric Company whereby the former will deliver 10,000 hp. of energy to the latter at a point in the Sacramento Valley, which will cause a saving of fuel oil, costing \$450,000 yearly. Electricity will be generated at the Copco plant on the Klamath River in Siskiyou County and will be transmitted nearly 300 miles before it reaches the system of the Pacific Gas & Electric Company.

MAPLETON, ORE.—The North Star Power Company is planning to erect 2 miles of transmission lines within the next 90 days. A. L. Shreve is manager.

PENDLETON, ORE.—The Helix Flouring Company has awarded contract to John Vaughan of Pendleton for the installation of a complete electric system for lamps and motors at its plant.

PORTLAND, ORE.—A permit has been granted to the Electric Steel Foundry, Twenty-fourth and York Streets, to erect a transformer station at its plant.

CORCORAN, CAL.—Preparations are being made by the San Joaquin Light & Power Company for the installation of an electric lighting system on Whitley Avenue. The lamps will be maintained by underground wires.

EL CENTRO, CAL.—Preparations are being made by the directors of the Imperial Irrigation District for the erection of an electric transmission line from Hanlan to a point on the Alamo River, to cost about \$11,000.

EUREKA, CAL.—As a result of the activity in shipbuilding industry at Eureka, the Western States Gas & Electric Company has taken on a large amount of business lately. The Hammond Company has abandoned its private plant, which operated its sawmill during the day, and will purchase energy from the Eureka division. The Rolph Company is doubling its electric power requirements and the new shipyard to be established in the city will require 400 hp.

LOS ANGELES, CAL.—Bids will be received by the Board of Supervisors of the County of Los Angeles until April 15 for moving and erecting boilers in the new power house at the County Hospital in the city of Los Angeles. Plans and specifications may be obtained at the office of the Board of Supervisors.

LOS ANGELES, CAL.—The contract for the installation of the ornamental lighting system on Broadway, between the tunnel and Tenth Street, has been awarded by the Board of Public Works to the Keystone Iron Works. The total cost of the work is estimated at \$65,000. The new standards will be 27 ft. high, each equipped with two inverted arc lamps.

LOYALTON, CAL.—The city of Loyalton is considering replacing the present turbine in the municipal electric plant with an impulse waterwheel in June. C. I. Simmons is general superintendent.

REDDING, CAL.—The Shasta Land & Timber Company of Redding, it is reported, will rebuild its electric power plant and planing mill, recently destroyed by fire. The loss is estimated at \$45,000.

VALLEJO, CAL.—Bids will be received at the Bureau of Yards and Docks, Navy Department, Washington, D. C., until April 22, under specification 2872 for furnishing two rotary connectors and switchboard for the navy yard at Mare Island, Cal.

DENVER, COL.—The Colorado Power Company of Denver has sold \$250,000 in capital stock, the proceeds to be used to pay for additions and extensions already made and for the construction of a steam power station in Sterling.

STERLING, COL.—The Colorado Power Company is contemplating the construction of a steam driven generating plant in Sterling.

LEWISTON, IDAHO.—F. S. Rice, president of the Union Copper Mining & Smelting Company, it is reported, has presented to the citizens of Lewiston a project to tunnel a mountain and divert the waters of the Salmon River of Idaho across the Horseshoe Bend in that stream in Idaho County, in connection with a hydroelectric power development. The project, it is said, has been financed. It is estimated that 62,000 hp. could be developed. The primary object of the company is the erection of an electrolytic smelter for the reduction of copper ores in the mountains in the vicinity of Horseshoe Bend.

DESERET, UTAH.—The Deseret Irrigation Company is reported to have closed a contract for the installation of a 100-hp. electric generating plant with the erection of 15 miles of transmission lines. In addition the company has placed contracts for the construction of a 250-hp. plant to be put in operation at a later date and operated in connection with the first project. The transmission lines of the company will extend from Deseret to Hinckley, Oasis and Abraham. Milton Moody is president of the company.

HELENA, MONT.—It is reported that the proposed manganese plant of the Anaconda Copper Mining Company at Great Falls will require approximately 21,000 kw., which is about one-half of the output of the Holter plant of the Montana Power Company, which, it is understood, will furnish energy to operate the manganese plant.

COLUMBUS, N. M.—The Columbus Electric Light & Power Company is reported to be considering the construction of a new electric plant to supply electricity in Columbus and Camp Furlong, to cost about \$30,000.

LORDSBURG, N. M.—The local engine house of the Southern Pacific Railroad Company was recently destroyed by fire, causing a loss of about \$500,000.

Mexico

TOLUCA, MEX.—The Molina de la Union of South America is planning to replace the present arc lamp street-lighting system with Mazda series lamps.

Miscellaneous

PANAMA.—Bids will be received at the office of the general purchasing officer, the Panama Canal, Washington, D. C., until April 23 for furnishing planished steel, sheet iron, spring steel, steel wire and cable, ignition cable, induction motors, etc. Blanks and information relating to this circular (1213) may be obtained from the above office or the offices of the assistant purchasing agents, 24 State Street, New York City, and 606 Common Street, New Orleans, La.

(Issued March 12, 1918.)

Record of Electrical Patents

Notes on United States Patents

- 1,259,381. COOLING SYSTEM: David D. Davis, Sw. Ave. Pa. App. filed April 25, 1914. Effective means of controlling the cooling action in transformers and rectifiers.
- 1,259,382. INSULATOR: Charles Le G. Fortesque, Pittsburgh, Pa. App. filed May 11, 1914. Supporting high-voltage lines.
- 1,259,384. INSULATING SUPPORT: Charles Le G. Fortesque, Pittsburgh, Pa. App. filed May 25, 1914. Improvements.
- 1,259,386. ELECTRICAL TERMINAL: Charles Le G. Fortesque, Pittsburgh, Pa. App. filed June 4, 1915. High-potential conductors.
- 1,259,396. VIBRATOR: Albert E. Hartwell, San Francisco, Cal. App. filed Oct. 16, 1916. Motor eliminated.
- 1,259,406. RELAY: Ernest H. Jacobs, Schenectady, N. Y. App. filed June 2, 1914. Protection to alternating-current electrical apparatus.
- 1,259,420. ARC LAMP: George M. Little, Pittsburgh, Pa. App. filed Oct. 3, 1913. Improvements in condensing chambers.
- 1,259,443. METAL-PETITCOAT INSULATOR: Karl C. Randall, Edgewood Park, Pa. App. filed Aug. 6, 1915. High-potential lines.
- 1,259,444. WINDINGS AND INSULATION FOR ELECTRIC APPARATUS: Emerson G. Reed, Wilkensburg, Pa. App. filed June 14, 1912. Small quantity of insulating material.
- 1,259,452. ELECTRIC CONNECTOR: George A. Burnham, Saugus, Mass. App. filed Oct. 1, 1915. Water-tight insulating inclosure.
- 1,259,453. ELECTRICAL DISTRIBUTION SYSTEM: George A. Burnham, Saugus, Mass. App. filed May 27, 1916. Split-conductor system.
- 1,259,454. TIME-LIMIT DEVICE FOR ELECTRIC SWITCHES: George A. Burnham, Saugus, Mass. App. filed Dec. 18, 1916. Improvement.
- (Issued March 19, 1918.)
- 1,446 (reissue). SELECTIVE RELAY: Frank L. Dodgeson, Rochester, N. Y. App. filed April 11, 1916. For controlling a highway crossing signal.
- 1,259,482. LOCKING LAMP SOCKET: Thomas H. A. Brown, Heidelberg, Transvaal, South Africa. App. filed Oct. 27, 1915. Improvements.
- 1,259,485. PROCESS OF MAKING ELECTRIC BATTERIES: Thomas W. Bytne, Boston, Mass. App. filed Jan. 7, 1916. Dry or semi-dry type.
- 1,259,496. TELEPHONE-CALL-DISTRIBUTING SYSTEM: Alfred H. Dyson, New York, N. Y. App. filed Jan. 30, 1913. Applicable to operating exchange.
- 1,259,512. INSULATOR: Charles J. Hellings, Los Angeles, Cal. App. filed Jan. 17, 1916. May be readily changed from a stationary insulator to a swinging insulator.
- 1,259,515. ELECTROMAGNETIC MEASURING INSTRUMENT: John S. Holliday, Wilkensburg, Pa. App. filed May 14, 1915. Adapted to determine the phase difference between electromotive forces.
- 1,259,516. SIGNAL DEVICE: Lewis S. Howard, Chicago, Ill. App. filed March 24, 1917. A simultaneously actuated signal carrier and shutter which co-operate to disclose the desired signal.
- 1,259,529. IGNITION SYSTEM: Lawrence Langner, New York, N. Y. App. filed Sept. 22, 1913. For internal-combustion engines of automobiles.
- 1,259,565. TRANSFORMER: Chester H. Thorndarson, Chicago, Ill. App. filed Jan. 24, 1913. Ventilates the coil by directing the passage of a cooling medium through determinate passages in the coil structure.
- 1,259,577. THERMOSTATIC SWITCH DEVICE: Fred W. Wolf, Chicago, Ill. App. filed Dec. 20, 1916. For controlling an electric circuit.
- 1,259,594. TREATMENT OF ZINC-BEARING MATERIAL CONTAINING IRON: Anson G. Betts, Asheville, N. C. App. filed April 21, 1916. Secures a high percentage of extraction of the zinc present.
- 1,259,597. DEVICE FOR PREVENTING TELEPHONE CORDS AND THE LIKE FROM TWISTING: John A. Breen, New Hartford, N. Y. App. filed Jan. 25, 1917. Improvements.
- 1,259,609. ELECTRIC ATTACHMENT PLUG: Harry W. Denhard, San Francisco, Cal. App. filed Oct. 31, 1911. Small number parts.
- 1,259,612. ELECTRIC LIGHT SOCKET: Leslie W. Friedel, Burlington, Iowa. App. filed April 5, 1917. Electric signs.
- 1,259,672. BRUSH GEAR FOR DYNAMO-ELECTRIC MACHINES: Harry D. Rohman and Frank R. Peters, New York, N. Y. App.

filed Feb. 16, 1917. Substitute for special pole-changing mechanism.

- 1,259,683. PROCESS FOR THE ELECTROLYSIS OF ALKALI CHLORIDES: Rolf van Hasselt, The Hague, Netherlands. Improvements.
- 1,259,696. HIGH-VOLTAGE-MEASURING INSTRUMENT: John B. Whitehead, Baltimore, Md. App. filed April 29, 1916. Voltage determined by the presence of corona.
- 1,259,736. CERTAIN-SHADE CIRCUIT CLOSER: John Hantay, Portland, Ore. App. filed May 18, 1915. Electric alarm.
- 1,259,744. ENGINE-STARTING SYSTEM: John H. Hunt, Dayton, Ohio. App. filed July 3, 1914. Improvements.
- 1,259,752. CONNECTOR: Guy M. Laird, Chicago, Ill. App. filed May 11, 1916. Detachable coupling for electrical conductors.
- 1,259,766. DISTRIBUTION BOX: Earl G. Negley, Canton, Ill. App. filed May 24, 1917. Electric light and power service.
- 1,259,788. MAGNETIC SEPARATOR: John G. Sekinger, Ford City, Pa. App. filed July 21, 1915. Effective in removing the iron and steel from the cullet.
- 1,259,816. VEHICLE LAMP: Charles M. Wilson, Elmira, N. Y. App. filed Oct. 7, 1916. Parts may readily be assembled or removed.
- 1,259,835. CONTROLLING SYSTEM FOR RECEIVING APPARATUS: Allen D. Cardwell, Brooklyn, N. Y. App. filed Nov. 19, 1913. Adapted to operate by impulses sent over a main line.
- 1,259,842. ELECTRODE HOLDER FOR ELECTRIC FURNACE: Paolo Fischer, Chicago, Ill. App. filed June 8, 1917. Improvements.
- 1,259,861. ELECTRICAL MAGNETIC DRIVE AND CLUTCH: David C. Henry, Rosebank, N. Y. App. filed March 22, 1916. Improvements.
- 1,259,862. TELEPHONE SYSTEM: Willi Herrmann, Berlin-Schoenberg, and Otto Stritter, Lichtenrade, Germany. App. filed Oct. 25, 1916. Improvements.
- 1,259,901. RELAY: Frederick R. Parker, Chicago, Ill. App. filed Feb. 19, 1904. Improved.
- 1,259,906. SERVICE-RECORDING INSTRUMENT: George H. Richards, New York, N. Y. App. filed Aug. 4, 1916. Electrically connected with machine.
- 1,259,907. INCANDESCENT LAMP: Thomas B. Rider, Los Angeles, Cal. App. filed May 2, 1917. Inserts automatically a new filament when one of the first-burning filaments burns out.
- 1,259,908. SIGNAL LAMP: Gordon E. Roeding and Edward B. Roeding, Detroit, Mich. App. filed Feb. 29, 1916. Motor vehicles.
- 1,259,915. ANNOUNCER OR INDICATOR: John L. Shahan, West Pullman, Ill. App. filed March 29, 1916. Improvements.
- 1,259,967. TELEPHONE SYSTEM: Alfred H. Dyson, Chicago, Ill. App. filed Sept. 6, 1906. Improvements.
- 1,259,995. SYSTEM OF SELECTIVE ELECTRICAL DISTRIBUTION: Charles F. Kettering and William A. Chryst, Dayton, Ohio. App. filed Nov. 20, 1912. Improvements.
- 1,260,008. TELEGRAPHIC SENDING MACHINE: Horace G. Martin, Rutherford, N. J. App. filed Aug. 4, 1917. Improvement.
- 1,260,010. DYNAMO-ELECTRIC CLUTCH: William Morrison, Des Moines, Iowa. App. filed Sept. 18, 1913. Self-generating type.
- 1,260,025. PROTECTOR FOR METER CONNECTIONS: Stephen R. Payson, Providence, R. I. App. filed July 29, 1916. Protects case where a cartridge fuse may be readily moved into position to bridge the service and meter terminals.
- 1,260,067. PORTABLE FLASHLIGHT: Julius Samach, New York, N. Y. App. filed Jan. 30, 1917. Non-short-circuiting holder.
- 1,260,070. STRANDED-CONTROL X-RAY SYSTEM: Louis W. H. Schimpf, New York, N. Y. App. filed March 15, 1917. Improvements.
- 1,260,071. STORAGE-BATTERY JAR: Earl T.

Schunmacker, Rapid City, S. D. App. filed Aug. 1, 1917. Improvements.

- 1,260,085. ELECTRICAL CONNECTOR: Parke T. Snyder, Chicago, Ill. App. filed Dec. 14, 1916. To provide a socket with a pair of contacts arranged in position for direct engagement.
- 1,260,094. POWER INDICATING AND LIMITING SYSTEM: John B. Taylor, Schenectady, N. Y. App. filed Oct. 27, 1914. Direct-current railway systems to which power is supplied by a plurality of sources.
- 1,260,152. NIPPLE: Mark V. Croker, Newton Upper Falls, Mass. App. filed Feb. 1, 1917. For water and gas pipes.
- 1,260,160. INSULATOR: Charles Disbennet, Logan, Ohio. App. filed May 8, 1917. Wire-retaining devices.
- 1,260,195. ELECTRICAL SPEED TRANSMISSION: Felix W. Hill, Proctor, Minn. App. filed March 14, 1916. No mechanical connection between the driving and driven members.
- 1,260,215. CONTROLLER FOR ELECTRIC MOTORS: Wilmar F. Lent, Philadelphia, Pa. App. filed March 26, 1917. Adapted to utilize a portion of the starting resistance for subsequent regulation.
- 1,260,218. CHARGING SYSTEM FOR STORAGE BATTERIES: James F. Lincoln, Cleveland, Ohio. App. filed Sept. 19, 1914. Automatic when connected to the battery.
- 1,260,224. RAILWAY ELECTRIC SIGNALING MEANS: Otto M. McLin, Bolivar, Mo. App. filed Jan. 27, 1917. Source of electric energy carried by the passing train.
- 1,260,230. ELECTROMAGNETIC SWITCH: Merle M. Mason, Cleveland, Ohio. App. filed June 11, 1914. Controlled by a light current.
- 1,260,236. COURSE INDICATOR: Willy H. R. Mildebrath, Jacksonville, Fla. App. filed Jan. 29, 1917. For motor vehicles.
- 1,260,252. ELECTRIC HEATER: Philip F. Apfel, Seattle, Wash. App. filed April 3, 1917. Inclosing case whose top wall is made of molded refractory earthy material.
- 1,260,263. ELECTRICALLY HEATED SOLDERING BOLT OR BIT: Francis Husband and Albert E. Woodhouse, London, England. App. filed Oct. 18, 1917. Improvements.
- 1,260,298. PHASE DISTRIBUTION FOR ELECTRIC FURNACES: Thaddeus F. Bailly and Frank T. Cope, Alliance, Ohio. App. filed Jan. 31, 1918. Three-phase supply is distributed to two electric furnaces.
- (Issued March 26, 1918.)
- 1,260,303. WIRELESS TIME SIGNALING: Edouard Belin, Paris, France. App. filed Oct. 24, 1914. Improvements.
- 1,260,317. CLOCK-CONTROLLED ELECTRIC CIRCUIT: James W. Bryce, Bloomfield, N. J. App. filed July 21, 1917. Improvements.
- 1,260,328. ELECTRICAL HEATER: Hoyt W. Chase, Indianapolis, Ind. App. filed July 21, 1917. For use with hand wheels.
- 1,260,354. PHYSICIAN'S ELECTRICAL APPLIANCE CONTROL: Herman G. Fischer and Peter P. Musket, Chicago, Ill. App. filed Jan. 11, 1915. Supply electric charges to vacuum electrodes.
- 1,260,355. VENTILATED SPARK GAP: Herman G. Fischer, Chicago, Ill. App. filed April 1, 1916. Improvements.
- 1,260,360. LAMP SOCKET: Edgar H. Freeman, Trenton, N. J. App. filed Jan. 6, 1915. Large voltage.
- 1,260,363. MERCURY RELAY: Maniquis Garl, Akron, Ohio. App. filed May 26, 1917. Electrical signaling apparatus.
- 1,260,379. ELECTRIC BATTERY: Clarence W. Hazlett, Lakewood, Ohio. App. filed Sept. 23, 1916. Secondary type.
- 1,260,380. SANITARY TELEPHONE-TRANSMITTER COVER: Shiro Higuchi, Los Angeles, Cal. App. filed June 4, 1917. Renders the telephone more sanitary.
- 1,260,381. POLYPHASE WATT-HOUR METER: Jacob H. Hodde and Otis White, Springfield, Ill. App. filed March 12, 1913. Two torque-producing elements are employed to drive a single shaft.
- 1,260,386. ELECTRICAL SYSTEM OF DISTRIBUTION: John W. Jepson, Buffalo, N. Y. App. filed Aug. 24, 1915. Improvements.
- 1,260,400. ELECTRIC FITTING: George C. Knauff, Chicago, Ill. App. filed Feb. 16, 1917. Improvements.
- 1,260,401. LAMP SOCKET: George C. Knauff, Chicago, Ill. App. filed Feb. 26, 1917. Electric fittings employing slidably mounted conducting elements.
- 1,260,412. TELEPHONE-EXCHANGE SYSTEM: Alben E. Lundell, New York, N. Y. App. filed Sept. 22, 1916. Semi-automatic.
- 1,260,413. LISTENING-KEY CIRCUITS: Alben E. Lundell and Franklin A. Stearn, New York, N. Y. Telephone-exchange systems.

Working to Ease the War Burdens

IT IS highly necessary that adequate steps be taken to place before the public service commissions all of the facts which testify eloquently to the war burdens borne by the public utilities. The work of the National Committee on Public Utility Conditions, representing the associations of utilities in the electric, electric railway and gas industries, is of first importance. Differences as to the general characteristics of these three classes of properties can safely be ignored for the time being; the important consideration just now is that they are all affected by higher costs of labor and materials. Rising costs and rigid rates threaten bankruptcy. If costs do not go down, rates must go up, or the net result will be insolvency for many properties. The problem is as plain as the trouble of the corner grocer who sees his margin grow slender. He promptly puts prices up. To do the same thing the public utility has to have sympathetic co-operation from the public service commission which has jurisdiction over it. Fortunately the truth is understood by a number of the commissions. Their members appreciate that the crisis is due to the war and that it calls for heroic treatment.

Electric Drive for Woodworking Machinery

EVERY industry brings its own problems to the electrical engineer. There is no universal solvent for all the difficulties which he has to meet, for not only every class of work but every individual example requires consideration by itself if the best economic results are to be obtained. General averages are of help in forming judgments, but they do not give the key to the individual problem. Some specific conditions which have to be met in the woodworking industry are pointed out in W. A. Black's discussion in the current issue of the motor drive found desirable in a particular plant. Woodworking machinery requires an exceptional amount of space on account of the bulky nature of both the raw material and the product. If laid out with the compactness sometimes very indispensable, it would be both inconvenient and costly to operate. Hence, if driven by the ordinary steam-power plant with its long lines of shafting and many pulleys, it wastes a great deal of energy on account of the scattered nature of the power distribution. It may turn out in fact that a long line shaft must be continuously operated for a few small machines. Many types of woodworking apparatus must be employed for the specific uses required

by the plant schedule, and these require extra room and more shafting, so that on the whole electric drive in woodworking shops has unusual opportunities for economy.

With individual motors the losses are practically directly proportional to the output of the machines doing useful work, and the uncertain factor now becomes the effect of the operating schedule on overhead cost. It was found, for instance, in the plant described by Mr. Black, that in certain places individual motors would prove to be uneconomical. For example, a battery of nailing machines used for box making gave its best economy through group drive. Each of the five machines constituting the group takes part in a continuous process, but the load of each is from its nature intermittent, and the group as a whole shows a conspicuous diversity factor, so that while each machine would have required when operated by itself a 2-hp. motor, one 5-hp. machine handles the whole group easily at good load and efficiency. To keep down losses the ball-bearing type of motor is used throughout, and it was found advisable to belt machines freely up through the floor from motors suspended from the ceiling below, thus shortening the belts and getting them out of the way. The ball bearings, too, proved to have an advantage in the abolition of the oil and grease which would otherwise cause a sticky coating of the inevitable dust found in woodworking plants. Motors can therefore be kept clean simply by blowing them out by compressed air. In one special case vertical-shaft motors were used to avoid the necessity of quarter-turned belts. Throughout the plant particular care seems to have been taken in adapting the type of motor, as well as its size, to meet the special requirements of the case. The result has been noticeable in the modest cost of operation and maintenance shown by three years of practical use.

A Big Canadian Steam Auxiliary

OUR readers will be struck by the ultimate development intended for the new steam plant of the Dominion Power & Transmission Company at Hamilton, Ontario. The company's main source of energy is a hydroelectric plant on the Welland Canal, about 35 miles (56 km.) from Hamilton, and this power is distributed over a wide area, being connected by three separate 45,000-volt lines to the main switching station just outside of Hamilton. The new plant is on the Lake Ontario waterfront near the load center of the entire system and is designed for an ultimate capacity of 75,000 kva. One-third of this is now installed in two

units. The equipment as designed not only furnishes auxiliary power but can be operated at high efficiency for additional output when it may become necessary. The layout of the plant is well shown in the elevation given. Provision is made for running the coal cars into a separate building, where they are unloaded into a receiving hopper; thence the coal is fed to a crusher and carried into the storage bins above the boilers by a conveyor. Thence again it is dropped to the under-feed stokers which serve the big water-tube boiler units. Both cooling and make-up water are obtained from the lake, the latter being subjected to a treating system before use.

The general layout of the plant is of the ordinary standard type, but each turbo-generator is normally supplied by a short pipe run from its own set of boilers, the piping being arranged so that one set of spare boilers will suffice for the entire plant. Each generator has its own motor-driven exciter, and a steam-driven exciter is held in reserve to be switched on to any machine in case of need. The generators are for 6600 volts, to be stepped up to 42,000 volts through transformers interconnected on the high-voltage side. The transformer arrangement is such that two sets of transformers will be connected to each pair of machines to localize trouble that may occur in either of them. Even power which is transmitted at 6600 volts is not taken directly from the generators but from the high-tension buses. As is commonly the case, the switching and transforming apparatus is in an annex to the main generator room. This the switchboard operator can overlook, he being stationed on the third floor of the switch house. The whole switching equipment is of the remote-control type, and in addition an ingenious set of signals between the boiler room, engine room and control room is organized with a combination of illuminated signs and Klaxon horns, thus appealing violently to two senses instead of trusting to one. The two transmission lines to the main switching line of the whole system pass from the roof of the transformer house and connect to the lightning arresters installed just outside. The station seems a singularly good example of recent practice in efficient design for operation on a large scale.

Ventilating Cable Ducts

THE rapid increase of industrial load in all our large cities puts heavy burdens on the underground distribution. There is a constant tendency to strain the capacity of the cables and increasing danger of breaking them down thereby, since there is a limit to the temperature which the insulation will stand without deterioration. The paper by William Keating and C. H. Mueller, abstracted in another column, gives a most instructive report of the results of overload and the possibility of increasing cable capacity by forced ventilation of the ducts. The particular duct line involved was one in Pittsburgh, less than a mile in length and called upon for heavy peak loads superimposed on a heavy regular load. In this particular line of ten ducts, eight of which were in use, there were no less than thirty-eight failures during the summer of 1916, in spite of the fact that the manhole covers were left off day and night. This showed plainly that the cable

heating was far above the permissible limit, which for the internal temperature on 11,000-volt cables is somewhere about 150 deg. Fahr. (65.6 deg. C.), the internal temperature being normally something over 50 deg. above that measured in the duct. After considerable discussion of ways and means it was determined to ventilate the duct artificially. This was ultimately done by installing eleven pressure blowers in alternate manholes, the intermediate holes being left open to allow the hot air to escape. The effect of these in working through the summer was to bring down the duct temperature just below 100 deg. Fahr., even then very near to the danger limit. In the cool weather of October the blowers were shut down and the manholes closed, and inside of a week the average temperature had gone up more than 20 deg., which caused a rapid resumption of forced ventilation. The temperature in the ducts was found by drawing in indicating coils of which the resistance showed the temperature, and these have proved of considerable service in investigating the conditions in various ducts so as to determine the available extra capacity if any. Some recording instruments were tried, but they proved to be too delicate for the rather hard service. This artificial ventilation of duct lines is, of course, a last resort, but one which may be not infrequently necessary at the present time when loads are high and cables higher. The experiments described by Messrs. Keating and Mueller are certainly of very considerable value in showing for the first time on a really practical scale what can be done if necessary to keep down dangerous temperatures in high-tension cables.

Radiation Losses in Pipes and Fittings

WITH all the effort that is now being made at economizing fuel to keep down operative costs of central stations the subject of radiation losses rises to considerable importance. There is, it is true, little uncovered high-pressure steam pipe now in use in central stations, but the covering on valves, flanges, feed pipes and other fittings is seldom complete or efficient. It is not always convenient to provide them with proper heat insulation, but it can be done without any particular difficulty while still leaving them accessible in case of necessity. The economic importance of the situation lies in the fact that an unprotected bit of pipe or valve gets rid of a large amount of valuable heat which ought to be conserved. At the present time fuel is so considerable a portion of the total expenses in a properly operated central station that savings here are of large importance. Those which can be effected by stopping losses after the steam is generated are of particular importance because they practically are equivalent to improving the boiler efficiency. If this chances to be low, the actual loss from unprotected pipe is particularly conspicuous.

There have been a good many investigations into the properties of insulating materials, but these have not been properly correlated with the possible savings in building up an efficient standard practice in steam-pipe covering. A very wide variety of materials have been used for this purpose. So far as yet discovered entrained air is the best of these. Free air forms a particular poor insulation on account of the heavy

losses by convection, but when it can be confined in the interstices of a material in itself a poor conductor of heat the combination is extremely efficient as an insulation. The intelligent development of heat-insulating material has therefore largely been guided by its capacity to hold air by reason of its porous structure. For practical use in steam plants the selection of material on account of this property is very much limited, for it must be heat-resisting over long periods of time, not changing its structure or losing its fundamental valuable quality by reason of the temperature to which it is exposed. This bars out many organic substances which in themselves possess most remarkable heat-insulating properties.

Losses due to imperfect insulation are startling to those who have not made any study of the subject. A square foot of bare pipe at the ordinary temperature of steam pipes wastes six or seven tons of coal a year, if in continuous operation. At present prices of coal this is a serious matter not likely to be passed over by operators of central stations. The plain moral is to use as short steam piping as is practicable and to insulate it with painstaking thoroughness even at exceptionally high cost of material, for the loss in fuel is a continuing one not unlikely gradually to increase, particularly if poor insulation is used, while to offset it there is only the fixed charge on the cost of proper insulation. It therefore would be well to avoid all unnecessary leaks and complication in a steam-piping system and to insulate it in all its parts with scrupulous care.

The Characteristics of Dielectrics

DIELECTRIC materials are of great practical importance to the electrical engineer because he has to depend upon them in the construction of his machines and of his conducting lines. Considering their importance, it is remarkable how little quantitative and systematic knowledge exists at present concerning the electrical properties of dielectrics. One reason for this deficiency lies in the complexity of the subject. In a dielectric of the simplest kind, assumed to be homogeneous and single, we have to deal with electrostatic stresses which must necessarily be very variable in space, except under ideally simple geometrical conditions. We have the conductivity of the material to deal with, also its inductivity, its dielectric constant and its dielectric strength. All of these properties, which are merely salient selections, are subject to possible variation with impressed voltage, frequency, temperature, time and previous history. When we come to consider compound dielectrics, formed of several substances in layers or juxtaposed masses, the problem of

electric behavior is likely to become very complicated. It is evident, therefore, that we must be content to study one phase of the subject at a time, in order to build up an engineering theory of dielectrics.

In C. A. Butman's article this week reference is made to the properties of two dielectrics well known to makers of electrical machinery; namely, fullerboard and paraffine oil. Some interesting experimental facts are recorded concerning these substances.

In regard to the fullerboard or pressspan slabs, the measurements indicate that, after being subjected to the treatment described, the conductivity of the material, as determined by the ratio of the dissipated watts to the square of the impressed voltage, remained roughly constant up to the gradient of 31.5 kv. per centimeter, which is indicated to be about one-ninth of the instantaneous rupturing gradient. In fact, the conductivity decreased somewhat as the gradient increased from 0 kv. to 31.5 kv. per centimeter. This result is rather remarkable. It is generally assumed that the conductivity of a dielectric is either constant or increases somewhat with the impressed gradient.

The second remarkable fact about these slabs is that their power-factor or phase-angle defect, measured in radians, diminished materially at a given temperature as the impressed potential gradient increased. Thus, at 91 deg. C. the indications of Fig. 2 are that the power factor was 0.095 at 3.15 kv. per centimeter and fell to 0.052 at 31.5 kv. per centimeter, the current strength through the slab increasing directly with this gradient. But since the conductivity of the slab is shown to have remained constant over this range, at least as a first approximation, it would seem that the inductivity, or specific inductive capacity, of the material increased very noticeably with the impressed gradient. If so, this is a noteworthy result, because it is generally supposed that the inductivity of solid or of liquid dielectrics at constant temperature is virtually independent of the impressed potential gradient.

As regards oil, the results indicate that the inductivity was, at least to a first approximation, independent of the impressed gradient up to 16.76 kv. per centimeter, but that it increased markedly with temperature, at first in straight-line fashion and then, beyond 50 deg. C., faster. It is also pointed out that the minimum dielectric strength of this oil occurred near the temperature of -12 deg. C.

These quantitative experimental results are valuable, not merely because they are rare, but also because they are expressed in simple metric units that all electrical engineers can understand. When dielectric properties are measured they are all too commonly concealed when expressed in terms of uncouth and antiquated units that not even English-speaking people can clearly understand.

SCARCITY of power is a serious factor in the present industrial activity.

It affects not only the central-station industry but also the output of supplies for the government by industries which depend on the great generating systems for energy. This situation will be considered in early issues. Among other subjects which will be treated are the standardization of overhead construction with a

The Coming Issues

view to reducing costs; shop repairs to distribution transformers in the interests of economy of time and money, and the performance of polyphase induction motors. In the latter article it will be shown that the choice of motor depends on considerations of load, starting and running current, frequency of starting and efficiency of operation.

The Characteristics of Dielectrics

Results of Investigations to Determine the Dielectric Constants, Strengths, Loss Angles and Energy Loss of Micarta, Fullerboard, Paraffine Oil and Other Substances—Effects of Potential Gradient and Temperature Found Very Important

BY CHESTER ARTHUR BUTMAN

FURTHER development of electrical apparatus is dependent chiefly on the provision of insulation which will withstand higher stresses and temperatures, the reduction of internal heating or the improvement of heat dissipation and the incorporation of electrical or mechanical features which will prevent damage from current surges. Since dielectrics are often the source of considerable heat when subjected to high potential gradients and since their characteristics are considerably affected by numerous factors, including temperature and electrical stress, it is necessary to have a very complete knowledge of the nature of dielectrics if they are to be applied properly. In what follows the writer will outline some of the properties he observed in an analysis of this kind, using a high-potential low frequency series inductance bridge.¹ Among the properties investigated were the dielectric constant, dielectric strength, dielectric loss angle, dielectric energy loss, conduction currents, and how these properties change with the potential gradient and temperature. Fullerboard and paraffine oil, used separately and combined, were the dielectric materials studied.

FULLERBOARD IN OIL

The fullerboard (presspan) which was tested was 0.32 cm. thick, uniform in quality and free from moisture. Before testing the samples were dried for three

time of breakdown appeared to depend on the formation of a certain number of bubbles at the electrodes. The writer is inclined to believe, however, that it is the time element rather than the formation of bubbles that determines the time of breakdown. The instantaneous breakdown potential was found to be 90,000 volts, which corresponds to a potential gradient of 283,500 volts per centimeter. The tests also showed that the samples would stand 30,000 volts (94,500 volts per centimeter) without breakdown at any temperature for an indefinite period.

Effect of Temperature on the Dielectric Loss Angle.—The relation between the power factor ($\sin \theta_x$) and the temperature with varying potential gradients (Fig. 1) can only be considered approximate because the temperature of the material under test lagged behind that of the oil in which the thermometers were placed and because an approximate formula was used to calculate the results. Nevertheless, the results are important because they show that the highest potential gives the lowest power factor. The results were verified by testing a sample at a constant high temperature.

Effect of Potential on the Dielectric Loss Angle.—Micarta and fullerboard were tested under identical conditions at a constant temperature of 91 deg. C., but no dielectric hysteresis was observed. The experiment showed further that the power factor² of micarta

FIGS. 1, 2 AND 3—HOW THE POWER FACTOR, DIELECTRIC LOSS AND CURRENT IN FULLERBOARD IN OIL VARY WITH TEMPERATURE, POTENTIAL GRADIENT AND THE SQUARE OF THE APPLIED POTENTIAL

days in a vacuum oven and placed hot in the oil tanks, where they were allowed to soak until saturated.

Dielectric Strength.—The dielectric strength was found to depend upon the time of application of the potential and the temperature. The principal effect of raising the temperature is to retard formation of gas bubbles around the testing terminals. In most cases the point of breakdown was just outside, and in only a few instances was it between the electrodes. This may have been due to the combination of three dielectrics at the terminals increasing the dielectric stress. The

increases with the voltage whereas that of fullerboard decreases (Fig. 2). It is thought by the author that this phenomenon may be due to the fact that the electrostatic field increases the polarization faster than it increases the ionization. Consequently the substance becomes a better dielectric when under electrostatic stress. From the curve it may be seen that the total current is directly proportional to the voltage.

Relation of Energy Loss to Square of Potential.—The

¹Described in ELECTRICAL WORLD for March 9, 1918.

²The fact that power factor of fullerboard decreases with an increase in potential gradient is confirmed by J. P. Minton (*Proceedings A. I. E. E.*, p. 1148, June, 1915).

energy loss is not strictly proportional to the square of the effective potential, as may be observed from Fig. 3. In fact, it increases considerably slower.

HETEROGENEOUS DIELECTRIC

A combination of alternate layers of fullerboard and oil, consisting of four oil-soaked fullerboards separated by three paraffine oil sections, was tested. Results plotted in Fig. 4 show that the dielectric constant of a heterogeneous combination of oil and fullerboard (4.25)

FIGS. 4, 5 AND 6—RELATION BETWEEN CURRENT, DIELECTRIC LOSS, POWER FACTOR, DIELECTRIC CONSTANT AND TEMPERATURE (TESTS ON ALTERNATE LAYERS OF PARAFFINE OIL AND FULLERBOARD ARE GIVEN IN FIG. 4; FIGS. 5 AND 6 REFER TO PARAFFINE OIL ALONE)

is greater than that of either component (3.32 for fullerboard and 3.69 for paraffine) taken separately and less than the sum of the two components. It may also be noted that the current, power factor, watts and dielectric constant increase with the temperature. At about 52 deg. C. there is a sudden increase in the rate of temperature rise due to a change in the physical properties of the oil at that temperature. Moreover, it was observed that the power factor of the heterogeneous combination was greater than that of fullerboard alone. Hence it appears that paraffine oil must have a large power factor at high temperatures. Since this seemed contrary to the usual belief, a dielectric loss test was made by hanging two parallel iron plates in an oil tank. This showed conclusively that the oil has a dielectric loss angle. Further experiments with aluminum plates showed that the dielectric loss angle of the oil is greatly increased by heating.

PARAFFINE OIL

Dielectric Strength.—To study the effect of change in temperature over a wide range some paraffine oil was frozen during an especially cold period and tested as it melted. The melting point (12 deg. C.) marked a transition point in the dielectric strength. Instead of decreasing with the temperature as would be expected, the dielectric strength³ began to increase.

Experiments were made on the dielectric strength of paraffine oil at high temperatures by use of a standard air spark gap placed in a tank of oil. Each point on the curve in Fig. 5 represents the average of ten breakdown values at the same temperature. The broken lines show the probable shape of the curve based on the results at low temperatures. The testing frequency was 25 cycles. It may be observed that the curves obtained with different sparking distances are similar. However, the transition point⁴ is 110 deg. C. with the larger gap, while with the smaller gap it occurs at 100 deg. C.

The most important results obtained from the experiments on the dielectric strength are that paraffine oil has a transition point at about 50 deg. C., and that the dielectric strength remains nearly constant at its maximum value from this temperature up to about 100 deg. C. At the latter temperature a third transition takes place and the dielectric strength falls off rapidly with an increase in temperature.

Heating of Oil Due to Dielectric Energy Loss.—Careful experiments showed that the heating of the oil due

to dielectric energy loss does not affect the principal properties appreciably.

Dielectric Loss Angle.—It may be observed from Fig. 6 that above 48 deg. C. the power factor increases more rapidly with the temperature with the higher potential gradients. The writer believes that this is due to the increased heating effect caused by the higher potential gradient. However, this effect is a small one and does not account for the large difference in the observed angles measured at different voltages.

It may also be noted from the curves in Fig. 4 that the dielectric loss angle increases rapidly with the temperature, that the highest gradient gives the greatest dielectric loss angle, and that there is a transition point in the power-factor curves at about 49 deg. C. This transition point occurs at nearly the same temperature as that in the dielectric strength.

In previous experiments Pungs⁵ discovered that paraffine oil has a large power factor at high temperatures. However, he was not able to detect a change in the dielectric loss angle due to an increase in the potential gradient which is so clearly shown in the experiments here discussed.

Dielectric Constant.—On account of the theoretical significance of the dielectric constant of paraffine oil, extreme care was exercised in measuring it. Contrary to expectations the dielectric constant of paraffine oil (Fig. 7) was found to increase with rise in temperature. Moreover, there is a transition point at about 50 deg. C., after which the dielectric constant increases still faster with the temperature.

It would also be of great theoretical interest if it could be shown that the dielectric constant changes with the potential gradient. The writer believes, however, that there is no such change (Fig. 7).

Currents in Paraffine Oil.—From Fig. 8 it may be observed that a transition point appears to occur in

³This observation had previously been made by Tobey, *Proceedings A. I. E. E.*, Vol. 29, 1910.

⁴T. W. Edmondson found that the dielectric strength of liquids was not directly proportional to the spark length.

⁵See L. Pungs, "Dissertation," Darmstadt, 1913; *Archiv für Elektrotechnik*, pp. 329-344, 1912; *Science Abstracts*, 16 B, No. 592, 1913.

the relation between the current and potential gradient at a higher temperature than for the dielectric loss angle. Upon analyzing the curves to see if the current is proportional to the voltage, an important result is revealed. If the currents are proportional to the voltage, the current at 4000 volts should be twice as great as at 2000 volts, and at 8000 it should be four times as great. The differences between the calculated and observed currents are given in the table printed on the opposite page.

The table proves that the current becomes proportional to the voltage at about 53 deg. C., which is the transition point for the oil. Below the transition this proportionality is departed from, the amount being greater the higher the potential used. From these results the conclusion is drawn that below the transition point there is not a sufficient number of ions to carry the current. The deficiency in ions increases indirectly with the temperature and directly with the potential used. Furthermore, the potential appears to cause the molecules to dissociate and form new ions. Since the currents below 53 deg. C. are strictly proportional to the temperatures, the dissociation appears to be proportional to the temperature. Hence it may be supposed that at the freezing point of the oil the mobility of the ions or the dissociation might be zero.⁶

The preceding ionic interpretations of results are strongly supported by the work of other investigators.⁷ In this connection it is also interesting to note that Bedell and Kingsley⁸ found a transition point in the insulation resistance of vacuum oil (a heavy paraffine

of 49 deg. C. is reached a transition point occurs.

Theory of the Dielectric Properties of Paraffine Oil.—The author believes that all of the dielectric properties of paraffine oil can be explained on the basis of the polarization and ionization. For instance, assume that the temperature increases indirectly as the polarization and directly as the ionization. Then the displacement current which depends on the polarization will decrease with rise in temperature, and the conduction current which depends on the ionization will increase. This relation appears to be in accordance with facts. The dielectric loss angle depends primarily on the polarization and consequently, to a certain extent, indicates its effects.

From a consideration of the analysis of the currents in oil it may be seen that the application of electrostatic stress causes an increased ionization in the oil. Above the transition point (50 deg. C.) ionization easily occurs, so that an adequate number of ions is provided to carry the current. Inasmuch as the dielectric loss angle increases at a more rapid rate above 50 deg. C., it appears that the polarization will decrease more rapidly after this point is passed. The higher rate of decrease in polarization allows the electrostatic stress to reduce the polarization more effectively through dissociation, so that the dielectric loss angle increases more rapidly above the transition point for any given potential.

Considerable light is thrown on the relative dielectric strengths of solids, liquids and gases by the works of other investigators.⁹ Faraday points out, for instance,

FIG. 7

FIG. 8

FIG. 9

FIGS. 7, 8 AND 9—VARIATION OF DIELECTRIC CONSTANT, CURRENT, AND LOSS IN PARAFFINE OIL WITH TEMPERATURE

oil) at 50 deg. C. They also found that the resistance of pure oils is a constant at any one temperature and decreases as the temperature increases.

Dielectric Energy Loss.—The dielectric energy loss is dependent on the characteristics of the capacity and the dielectric loss angle which have already been discussed. It may be seen in Fig. 9 that the loss is proportional to the temperature. Inasmuch as the dielectric constant is independent of the voltage, and since the dielectric loss angle increases with the voltage, the energy loss in paraffine oil increases faster than the square of the applied potential. When a temperature

why the intensity of induction required for breakdown must be much higher in a fluid than in a gas and still higher in a solid than in a fluid. Thornton showed that the dielectric strength decreases as the frequency increases. The time element involved in the rupture of dielectric was pointed out by several researchers, Townsend saying that a certain number of ions must be formed by collision before discharge can take place. Chernyshoff and the writer showed that a low-frequency (60-cycle) discharge follows the shortest path, whereas at high frequency there is not sufficient time for ions to be formed by collision, so the discharge may follow a longer path.

The change of dielectric strength of the oil with temperature is satisfactorily explained by the ionization theory. The highest dielectric strength occurs when the ionic conduction begins to take place freely. From

⁶L. Maclès (*Comptes Rendus*, 151, p. 63, 1910) found that vaseline acts as a medium containing free ions whose mobility is zero in the semi-fluid state, but observable in the liquid state. In the same periodical (161, pp. 694-696, 1915) Maclès determined the conductivities of certain insulating liquids from the velocities of recombination, concluding that strong fields reduce the conductivity.

this point to about 100 deg. C. the dielectric strength is nearly constant; thus it appears that the liquid is polarized, otherwise it would be difficult to see why the dielectric strength remained nearly constant as the temperature increased. However, if the liquid is polarized it would seem that the same stress would have to be applied until the polarization itself was changed. At the transition point of 50 deg. C. and at higher temperatures there are enough ions to carry the current and the ionic conduction protects the polarization. However, the curves of Fig. 5 indicate that the polarization decreases slightly as the temperature increases until about 100 deg. C. is reached, after which there is a rapid decrease in the dielectric strength. According to the preceding theory, the polarization should decrease rapidly as the temperature increased beyond 100 deg. C. This was proved by C. W. Ackerman,¹⁰ who found that paraffine oil becomes a bad insulator at about 100 deg. C. In this connection it is interesting to observe from the two curves that the breakdown point of polarization occurs at the lowest temperature in the one in which the polarization decreases the fastest.

Below 50 deg. C., the polarization is protected less and less by the ionization until the freezing point is reached, at which point there are probably few if any mobile ions. Hence the freezing point (—12 deg. C.) marks the point of minimum dielectric strength. As the temperature is decreased below —12 deg. C. the oil assumes new physical properties in which the dielectric cohesion and consequently the dielectric strength is greatly increased.

CAUSE OF THE INCREASE OF THE DIELECTRIC CONSTANT WITH THE TEMPERATURE

It would be expected that the dielectric constant would decrease as the temperature increases because there is less matter between the condenser plates at high temperatures. For some substances¹¹ this is so.

However, in the case of paraffine oil it is not sufficient to take into account only the density, because the polarization and ionization are also important factors. The density and polarization both decrease with an increase of the temperatures, so that in the case of paraffine oil the cause of the increase of the dielectric constant must be due to the increase of the ionization with the temperature. When the molecules dissociate an increased stress appears in the ether which is due to the attraction of the free charged atoms. This makes it easier for the lines of the applied electrostatic stress to pass through the liquid, thereby increasing the dielectric constant. This factor appears to predominate over the other two.

The preceding view is confirmed by experiments which showed that the change of the ionization and the dielectric constant with the temperature run parallel. For instance, the point (50 deg. C.) at which increased ionization occurs is the point at which the dielectric constant begins to increase faster with the temperature. However, the dielectric constant is not dependent primarily on the conductivity, for a substance may have a dielectric constant apart from conductivity. For instance, the author tested a sample of micarta made by

a special experimental process near its breakdown value (95.8 deg. C.). It was a conductor because the dielectric loss angle was nearly 90 deg., but it still had a dielectric constant which measured 34.37. At 65 deg. C. and with the same gradient the micarta had a dielectric loss angle of 21 deg. 39 min. 35 sec. and a dielectric constant¹² of 7.979. The difference between a dielectric and a conductor is clearly defined in the author's paper on the series inductance bridge.

NATURE OF A DIELECTRIC

Dielectric phenomena have to do primarily with the distribution and characteristics of polarized molecules; that is, molecules charged on one side positively and on the other side negatively. That the dielectric con-

stant is a molecular property is shown by its direct relation to other purely molecular properties such as the index of refraction, dispersion, absorption and the capillary constant.

A theory regarding the nature of polarization has been proposed by W. M. Thornton¹³ which does not appear to be at variance with these experiments. He found that polarization, no matter how long continued or slow in action, is quasi-elastic in type. There are three stages. The first involves rapid changes and results in the rearrangement of the atomic charges within the molecule. During the remaining two stages an electrical strain is established throughout the mass under the new conditions of internal stress imposed by the first polarization.

In the case of gases and liquids an explanation of the dielectric phenomena must not be given on a static basis, but on a kinetic one. This is necessary because of the change of the dielectric constant with the temperature, the time necessary to produce electrostatic effects and the known movements of molecules in gases and liquids. Finally the properties of dielectrics may be influenced by their being ionized, as has been shown to be the case for paraffine oil in the foregoing experiments.

The experimental part of this paper was done at the high-tension research laboratory of the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., of which C. E. Skinner is director.

¹²F. Sanford (*Science*, pp. 759-760, May 26, 1916), presents the dielectric constant of certain metals. E. A. Harrington ("Dissertation," Clark University, *Physical Review*, Vol. 8, p. 591, 1916) states that water has a dielectric constant "entirely independent of the conductivity."

¹¹M. A. Lorentz (*Ann. der Phys.*, 9, p. 641, 1880) proposed to represent the variation of the dielectric constant K with the density d by the formula $[(K-1)/(K+2)] \times 1/d = \text{constant}$, which has been verified recently by A. Occhialini, *Nuovo Cimento*, 7 Ser., 6, pp. 108-126, 1914.

PRESENT CONSTRUCTION AT WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY'S NEW PLANT

New Works of the Westinghouse Company

Plant at South Philadelphia, Started in 1917 and Now in Partial Operation, Designed for
Eventual Expansion to Size Comparable with
East Pittsburgh Works

FROM a plowed field less than a year ago to an industrial plant embracing at present seven large buildings and employing over 1800 people, engaged in manufacturing ship-propulsion machinery for the government, is the record at the new South Philadelphia works of the Westinghouse Electric & Manufacturing Company.

The East Pittsburgh plant began operations in 1895 with about 2000 employees, and it now employs in the neighborhood of 25,000 people and occupies more than 100 acres (40 hectares) of floor space, a development beyond which it was not deemed to be practicable to expand.

After thorough investigation of available sites during the summer of 1916, the property at Essington, or South Philadelphia, was chosen. The land, embracing 500 acres, is on the Delaware River, in Delaware County, Pennsylvania, 9 miles (14.4 km.) south of Broad Street Station, Philadelphia, adjoining the Hog Island shipyard of the American International Corporation. It is reached by the Philadelphia & Reading and Pennsylvania railroads and by the Chester short line of the Philadelphia Rapid Transit Company. Its location on the river, on which there is a frontage of 4500 ft. (1371 m.) also affords another means of transportation, though as yet no docks have been built.

This location insures adequate fresh water for power-house operation and tests on the turbines and auxiliaries to be built.

Construction was begun early in 1917. In November the plant began operations on a small scale, and these operations have been gradually increasing.

The entire activities at present are devoted to the manufacture of steam turbines, condensers, gears and other accessories used in the equipment of ships, the most vital immediate need of the government. Marine propelling machinery is being built for the Submarine Boat Corporation and the Merchant Ship Building Corporation as agents for the Emergency Fleet Corporation. Turbines and reduction gears are also being built for use by the United States Navy on torpedo-boat destroyers.

It is expected that eventually the plant will be expanded until it is comparable with the East Pittsburgh works. A portion of the tract has been set aside for

a town site that will afford space for approximately 5000 people.

Already seven buildings have been erected. These include the pattern storage shop, foundry, forge shop, power house, erecting shop and two machine shops, representing over 600,000 sq. ft. (55,200 sq. m.) of floor space.

Practicing a policy consistently advocated by the company, the management determined to use central-station power. This energy is supplemented by the company's own power plant.

The demand on the Philadelphia Electric Company, which supplies this district, is naturally greater in winter than in summer; it has a surplus capacity in the latter period. On the other hand, the Westinghouse company requires steam heat at from 2 lb. to 4 lb. (140 to 280 grams per square centimeter) pressure for heating buildings during the winter, but requires no steam during the summer except for testing. Steam for heating can be most economically supplied by passing it through a non-condensing turbine and then to heating mains after it has done its work in power generation. An arrangement satisfactory to both companies was entered into by which the Philadelphia Electric Company supplies the works with energy during the summer, and in the winter energy will be generated in the power plant at the works, which, on account of the exhaust steam being utilized, is operated non-condensing. This arrangement affords a reserve source of power, and, when necessary, the local plant may pump back power into the central-station system.

Selection of the site and general direction of the plant activities have been in charge of H. T. Herr, vice-president Westinghouse Electric & Manufacturing Company, who also superintended the securing of all the equipment.

Business relations with Westinghouse, Church, Kerr & Company, who are constructing the plant, were handled by Calvert Townley, assistant to the president, technical arrangements being subject to Mr. Herr's approval. As assistant to Vice-president Herr, R. B. Mildon had general supervision of construction and the providing of equipment, as well as its operation. All arrangements have been subject to the approval of E. M. Herr, the president.

Features of Steam Plant Supplementing Water Power

Station Designed for 75,000-Kva. Ultimate Rating Feeds Hamilton, Ontario, and 42,000-Volt Transmission Lines in Territory Between Lakes Erie and Ontario

A 75,000-KVA. steam generating plant, known as the East End power station, has been built recently by the Dominion Power & Transmission Company, Ltd., at Hamilton, Canada, to supplement its hydroelectric plant at Power Glen. The new station is designed for continuous and even independent operation at high fuel economy and is not intended solely for use as an emergency standby station. It is situated on the Lake Ontario waterfront, where plenty of condensing and boiler-feed water as well as fuel is available.

At present the company's chief source of energy is the hydroelectric station at Power Glen. This plant is situated about 35 miles (56.3 km.) from Hamilton, on the Welland Canal, and develops its power from water taken from Lake Erie under a head of 265 ft. (80.8 m.). Power is supplied to subsidiary companies in the Welland, St. Catharines, Thorold, Port Colborne, Grimsby, Dundas, Brantford, Oakville and Hamilton districts, the largest portion going to the city of Hamilton. So as to minimize interruptions to service three separate lines operating at 45,000 volts are employed to connect the Power Glen plant with the main switching station at Bartonville, a suburb of Hamilton. The accompanying map shows the district served by the Dominion Power & Transmission Company and also the proximity of the newly completed steam plant to the load center of the system.

While the steam station is designed for 75,000-kva. ultimate rating, only 25,000 kva. has been installed so far. The station delivers energy to the 45,000-volt lines of the company, but in addition is designed to fulfill the requirements of a step-down transformer station, as 13,000-volt energy has to be distributed to neighboring factories. Half of the 25,000-kva. step-down equipment is installed.

During the winter months it is necessary to house the coal-hauling equipment, so a separate building is provided for this purpose into which the cars are run and unloaded into a large receiving hopper. From

this hopper the coal is fed to a crusher and then elevated by an inclined conveyor to storage bins above the boilers. From these it may be fed by gravity into a traveling hopper, which weighs it and delivers it to the stokers.

The boilers (1050 hp. each), which are of the Edge Moor type, are equipped with eleven-retort Taylor underfeed stokers and radial brick chimneys 240 ft. (73.2 m.) high, a combination which will allow the boilers to be forced to 300 per cent normal rating if necessary. Automatic soot blowers and boiler-room instruments which will permit the engineers to operate the boilers intelligently are provided. Make-up water for the plant is obtained from Burlington Bay and is treated by the We-Fu-Go system, the apparatus being situated in a separate building.

FIG. 1—TERRITORY SERVED BY DOMINION POWER & TRANSMISSION COMPANY

Each of the turbine generators, which are of the Westinghouse Parsons-Curtis type, is supplied with steam from its own set of boilers through piping run through the basement wall. The piping is arranged so that one set of spare boilers is sufficient for the entire plant. Steam is delivered to the turbines at 200 lb.

FIG. 7—MAIN GENERATORS AND MOTOR-DRIVEN EXCITERS

(11.1 kg.) pressure and 160 deg. superheat. Surface condensers are installed immediately below each turbine, the condensate and air being withdrawn by pumps coupled to an impulse turbine. Cooling water for the condensers is also taken from Burlington Bay, the pumps being installed below the water level so as to be self-priming. Exhaust steam from the turbines driving the auxiliaries is admitted to Cochrane open-type feed-water heaters. The boiler-feed pumps are also turbine-driven, and each one is large enough to feed four boilers under maximum load.

The turbines drive 12,500-kva., 6600-volt, three-phase, 66⅔-cycle generators, which are cooled by air treated in Carrier humidifiers. Two humidifiers will be provided for each set of three generators. Each generator is separately excited by a motor-driven exciter, although a steam-driven exciter is also available for any machine in case of necessity.

TRANSMISSION OF POWER

Energy from the generators is carried by twelve 500,000-circ. mil lead-covered cables to switches in the control room and then to 6600/42,000-volt transformers which are interconnected on the high-voltage side. With this arrangement two sets of transformers are always between each pair of machines and disturbances are localized in case of trouble in any one of the generators. Power, which must be transmitted at 6600 volts, is not taken directly from the generators but from the 42,000-volt bus through step-down transformers. Energy for station service, however, is taken directly from the generators through step-down transformers. The station-service buses are sectionalized in order that equipment which is used exclusively with each generator may be operated therefrom. Provision is made for supplying general station service from any generator.

All of the electrical apparatus is remotely controlled

As shown by the cross-section of the plant, the switching and transforming equipment is installed in a low building adjoining the power plant. Views of the 42,000-volt oil-switch room, a section of the 6600-volt bus compartments and the transformer bays are shown

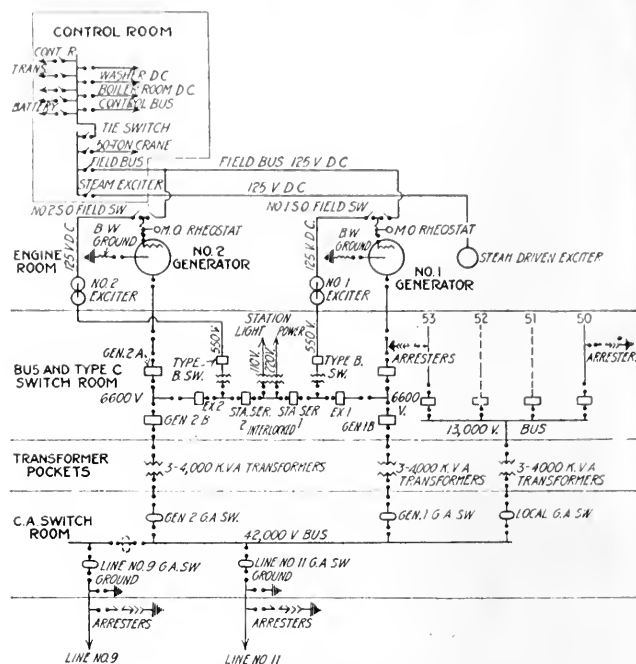

FIG. 8—TRANSFORMERS TIED TOGETHER ONLY ON HIGH-TENSION SIDE

in accompanying illustrations. Two transmission lines pass through the roof and carry energy to the main switching station at Bartonville. The lightning arresters protecting the steam station are installed beneath the terminal structure just outside the switch house.

Solving Woodworking Drive Problems

Method by Which One Company Has Practically Eliminated Repairs and Reduced Power Bills by the Proper Selection of Drives and Correct Mounting of Motors

BY W. A. BLACK

Engineer Fairbanks, Morse & Company

WOODWORKING is one industry in which the advantages of motor drive over shaft and belt drive are very marked. Electric drive is especially desirable because the machines can be located for the most convenient handling of the products and because long shafts will be required with group drive if the machines are scattered to permit the piling of stock and finished products. Furthermore, much of the machinery is used intermittently for comparatively

In planning the drive it was found that there were certain places where individual drive would not be economical. For instance, the battery of nailing machines shown in Fig. 1 were arranged for group drive because a careful study showed that the load is intermittent and that seldom more than one machine is required to do actual work at any one instant. If individual drive had been used, a 2-hp. motor would have been required for each machine and the motor would have been loaded only intermittently, giving a very low load factor with its resultant low power factor and efficiency. With the arrangement adopted a 5-hp. motor drives the battery of five nailers, running with approximately steady load at approximately full load and giving a higher power factor and efficiency than the small machines even had they been operating at full load.

Another factor influencing the choice of group drive was that in this work the machines are never operated as individual units, but each machine performs its part of a progressive operation. The machines are used for making boxes, two end machines being used for framing the boxes, the next two machines for nailing sides, and the center machines for nailing the bottom of boxes coming from each side. The boxes finished by center machine are loaded on a truck placed within reach of the operator.

FIG. 1—GROUP-DRIVEN BATTERY OF NAILING MACHINES

short periods, resulting in considerable transmission loss if shaft and belt drive is used.

All these conditions in a line-shaft-driven plant tend to increase the power lost in transmission, because the long lines of shafting must be run continuously in order that power may be available for all machines when it is wanted, though comparatively few are in operation at one time. This loss is increased by the friction of loose pulleys on machines that are not working. With a motor-driven plant having for most purposes individual drive transmission losses are very small because they are almost directly proportional to the number of machines that are doing useful work.

The conservation requirements of the present time have shown that the electric drive alone is not sufficient, but that the type of motor chosen and the method of drive used must be designed for the highest efficiency.

WHERE GROUP DRIVE WAS ADVISABLE

The Riddle-Rehbein Manufacturing Company of St. Louis has laid out its drives with such care that practically all objectionable features of the ordinary woodworking plant have been eliminated and energy bills are less than for similar plants of smaller output. In most cases individual drives are used, as with this method the motors remain idle except at such times as the machines are in use.

VALUE OF SUBSTANTIAL FOUNDATIONS

The 30-in. (76-cm.) double surfacer shown in Fig. 2 is direct connected to a 50-hp., 1200-r.p.m. induction

FIG. 2—30-IN. DOUBLE SURFACER DIRECTLY CONNECTED TO 50-HP., 1200-R.P.M. ROLL-BEARING MOTOR

motor. The planer and motor are mounted on I-beams embedded in a concrete foundation which extends through basement into solid ground. Six hundred and fifty cubic feet (18.2 cu. m.) of concrete was used in the foundation, but the expense of making it is well offset

by the freedom from vibration and the perfect alignment maintained thereby. The advantage of a firm foundation cannot be overestimated, especially for direct connected machines. The foundations should be large enough to accommodate both the machine and the driving motor, as failures have occurred where a machine and the driving motor were mounted on sepa-

FIG. 3—TWO-SPINDLE SHAPER BELTED TO TWO VERTICAL MOTORS; BELT-DRIVEN BAND SAW IN FOREGROUND

rate foundations, owing to foundations moving with reference to each other and thus throwing the machines out of line.

The advantages of a solid foundation for maintaining perfect alignment are well illustrated by the performance of a 54-in. (137-cm.) resaw, which was mounted on a substantial foundation and directly connected to a 35-hp., 600-r.p.m. motor. After being in service over four years, the machine, with a tension of 2000 lb. (907 kg.) on a saw, would run for two minutes and thirty seconds after the power was shut off. With a less substantial foundation the heavy machine would have vibrated out of line and the strain on the bearings would have caused excessive repair expenses.

Direct-connected ball-bearing motors reduce the maintenance expense cost to a minimum. There are no belts to slip, break or be taken care of. The ball bearings are contained in dust-proof inclosures requiring only infrequent attention compared with other types. With such motors and bearings the greasy dust so prominent in most woodworking plants can be avoided. Furthermore, the absence of oil and grease on motor frame and windings makes it possible to clean the machines by blowing off the dry dust. For the purpose of cleaning machines the woodworking company has a small motor-driven air compressor which is in use only when the cleaning is necessary.

While machines which are belted to motors mounted on the ceiling have all of the advantages of individual drive, they have the disadvantage that the belts obstruct the light. In addition, since the belts are long, they require more attention and are harder to cover

with protective guards. To overcome these objections many of the motors in this plant were mounted on the ceiling under the driven machine and a belt was run through an opening in the floor. This arrangement had all the advantages of ceiling mounting and at the same time permitted the use of short belts that could be easily protected by guards. No changes were necessary in the bearing construction as ball bearings were used and only occasional attention is required. With this type of drive it was necessary to guard against the use of excessively short belts and against the location of motors directly under driven pulleys, as these conditions would reduce the area of contact of belt on pulleys.

VERTICAL SHAFT MOTORS FOR SHAPERS

A very practical drive shown in Fig. 3 was adopted for the two-spindle shapers used in this plant by belting them to two 3-hp., 1800-r.p.m. vertical motors. The starting switches are mounted on side of machine opposite the motor within reach of the operator. Either or both spindles can be readily started or stopped as required. The use of vertical motors eliminates the need of crossed belts, and the ease with which spindles can be started and stopped reduces the tendency for the operator to leave spindles in operation when not in use.

On a small jig-saw used for cutting out ornamental work the lines of which have to be followed very closely a unique arrangement is used to keep the work free from sawdust. A small ball-bearing motor is belted to a blower, which in turn is connected by flexible tubing to a nozzle placed close to the work. The air from the blower is forced through the nozzle, which blows all sawdust from the work and leaves the lines visible.

FIG. 4—GROUP OF SMALL MOLDERS BELTED TO BALL-BEARING MOTORS

Some small molders belted to ball-bearing motors are shown in Fig. 4. For this illustration the motor covers were removed to give a clear view of the motors. It is worthy of mention in this connection that with ball-bearing motors it is practicable to cover the motors as it is not necessary to remove the covers frequently for oiling.

A drive which required careful consideration before it was successfully worked out was that of a Linderman automatic dovetail glue jointer driven by a 15-hp., 1200-r.p.m. motor. In cold weather the high torque necessary to start required either a larger-size squirrel-cage motor or a motor of the wound-rotor type. With the larger squirrel-cage motor the starting current would have been objectionable and the power required would have only lightly loaded the motor after the machine had attained full speed. The wound-rotor type of motor with a secondary starter would have overcome the difficulty of operation but would have imposed the necessity of more care owing to slip rings, brushes and starter contacts.

The drive was very successfully taken care of with an internal starter motor. With this motor it was possible to obtain a high starting torque with a low starting current in a reasonably short starting period. The starting switch was simply a single-throw switch, and slip rings and brushes were eliminated. The installation has been in operation for over three years and has given perfect satisfaction.

A great deal has been written about the proper methods of mounting and the correct drive for the different classes of machines. In the above article the writer has endeavored to show how one company practically eliminated repairs and reduced power bills by the correct drive and by the correct mounting of its machines. What it has done can be equaled by any other company.

ACCOMPLISHING REDUCTION OF DUCT TEMPERATURES

Results of Investigation Carried On in Order to
Determine How Effective Air Blowers Are
in the Cooling of Cable Ducts

INVESTIGATIONS to determine how much air blowers can reduce the temperature of ducts used for high-voltage transmission cables have been made by William Keating and Carl H. Mueller of the Duquesne Light Company of Pittsburgh, Pa., some of the conclusions being presented herewith. Study along this line was precipitated by a rapid increase of load on the company's 11,000-volt system which caused whole sections of the duct line to become so badly overheated that numerous cable failures occurred.

In commenting on the subject of safe operating temperature the investigators pointed out that cables must operate at a much lower temperature than any other kind of electrical apparatus to assure reliable service. It has been definitely determined by laboratory tests that the maximum safe working internal temperature of an 11,000-volt cable is 150 deg. Fahr. (65.6 deg. C.). Beyond that temperature a peculiar phenomenon is manifested. By reason of the high voltage a hysteresis effect occurs in the insulation that generates heat. Up to 150 deg. Fahr. this loss increases directly with the temperature, but after 150 deg. Fahr. is reached the curve takes a very sharp upward turn and quickly reaches the failure point. Safe operation depends, therefore, upon the ability to keep the internal cable temperature below 150 deg. Fahr. By laboratory tests it has been determined that the difference in tempera-

tures between the duct wall and the copper of the cable is approximately 54 deg. Fahr.

FACTORS AFFECTING CABLE LOAD

The number of cables in a given duct line and the character of the soil through which the ducts run are factors that determine the amount of load the cables can carry. The characteristics of the soil determine the rapidity with which the heat can be dissipated, while the number of cables determine the amount of heat to be dissipated. In general 35,000 kva. is the maximum load any duct line should be called upon to carry. Several parts of the Pittsburgh system have exceeded this safe maximum. It is at these points that trouble has developed.

In one section where trouble occurred there are ten tile ducts, built two wide and five deep, in which there are installed eight No. 4/0 three-phase, 11,000-volt cables. The street is narrow and its soil has poor heat-dissipating qualities. Several rolling mills with annealing furnaces are close to the street. Every cable

in the run is called upon to carry from 200 amp. to 220 amp. during the morning and evening peaks. In the summer the load factor is about 50 per cent and in winter about 75 per cent.

WATER VERSUS AIR FOR COOLING

During the summer of 1916 there were thirty-eight cable failures in this section, which is somewhat less than a mile long. All these failures occurred between June 1 and Oct. 1; in other words, during the hot weather. In order to relieve the situation, the man-hole covers were removed and left off day and night during this period. During the winter of 1916-1917 plans were formulated for the coming summer for cooling this section if it should be found necessary. Two plans were discussed—first, cooling by circulating water; second, by air from motor-driven blowers. The first idea was abandoned on account of the danger of cable failures from electrolysis, a trouble which has always been prevalent in this district.

At first the use of air blowers was not very favorably looked upon, as there were so few vacant ducts in the subway that there was very little free air to move. However, as this was the only plan left it was decided to try it out. Therefore eleven blowers, each having a capacity of 612 cu. ft. (17.1 cu. m.) per minute, were built into wooden frames to fit the manholes. Rubber-

covered wire was run through one of the spare ducts to supply energy to operate the blowers. At first the blowers were arranged to draw the air out of the duct line, but this overloaded the motors on account of the restriction of the passage of air through the duct line. The process was reversed and outside air forced into alternate manholes, the intervening holes being left open to allow the escape of the hot air. The effect produced is shown graphically in the accompanying curve. The average maximum temperature during the summer, with the blowers running, was 96 deg. Fahr. (35.6 deg. C.), which is just within the safe operating temperature.

By October the weather had become considerably cooler, so it was decided to shut down the blowers and close the manholes. This was done, and within a week the temperature had increased from 96 deg. Fahr. to 119 deg. Fahr. (35.6 deg. C. to 48.3 deg. C.). The manholes were opened and the blowers replaced. This increase, occurring as it did during cool weather, is due to the higher load factor on the cables. As the load is constantly increasing it may be possible that the blowers will have to be operated until the arrival of very cold weather.

Only two breakdowns have occurred in this section since the blowers were installed, and these were due to individual overloads on the cables caused by station failures at other parts of the system.

While the use of blowers is, no doubt, largely responsible for the decrease in the number of failures, the weather was cooler during the summer of 1917 than 1916. Furthermore, the load was slightly less, owing to the increase in the capacity of the transmission system at other points. The neutral has also been grounded, and this, it is believed, has aided in decreasing the number of failures in general as the voltage between conductors and ground has been decreased from 11,000 volts to approximately 6800 volts.

METHOD OF DETERMINING DUCT TEMPERATURE

The method of determining the temperatures in duct lines may be of interest and hence is given here. Several indicating pyrometers, depending on the change of resistance in a small coil, were purchased and drawn into the duct lines at the ends of 250-ft. (76.2-m.) leads. These instruments read within 2 deg. of accurate and are rugged enough to stand the service required of them. With these instruments surveys were made of all duct lines which might possibly become overheated and records kept of the temperatures. By this means the investigators have been able to determine where duct lines are already loaded to maximum capacity and thus to say where no more cables should be installed. Recording pyrometers built on the same principle as the indicating instruments were also used, but with little success. Such instruments were found so extremely delicate that they would not stand the service required of them. A number of twenty-four-hour charts were obtained at danger points, but the instruments could not be placed in regular service.

There is much to be done yet in the way of experimenting to secure data on which conclusions can be based. Heretofore this company has been restricted to the use of laboratory data compiled by cable manufacturers, which at best can only approximate actual conditions.

BUREAU OF STANDARDS AND ILLUMINATING ENGINEERING

Dr. M. G. Lloyd Addresses Chicago Meeting on Relation of the Bureau to Illuminating Engineering
—New Federal Lamp Specifications Given

In an address entitled "Relation of the Bureau of Standards to Illuminating Engineering," Dr. M. G. Lloyd of the bureau's engineering staff, Washington, D. C., presented to the Chicago Section of the Illuminating Engineering Society a thorough and valuable review of the activities of the bureau most interesting to illuminating engineers. The paper contains an analysis of the field of the illuminating engineer, an outline of the work of the Bureau of Standards, a discussion of the standards for the measurement of light both in this country and abroad, a statement of the bureau's work to determine a standard in color specifications, a detailed description of the bureau's method of testing lamps purchased by the government, a tabulation of the new government lamp specifications, a discussion of the properties of gas-mantle lamps, an analysis of the bureau's work in testing automobile headlight lenses, a description of an extensive investigation carried out to determine the sensibility of the eyes of different individuals to light of different colors, and a statement of the bureau's activities in connection with public utility standards.

In discussing the scope of the illuminating engineering field, Dr. Lloyd said: "Illuminating engineering involves not only the application of physics, but it must consider also the physiology and psychology of light; that is, the relation of light to the human being. Illuminating engineering also involves architecture, interior decoration, hygiene and therapeutics. The work of the illuminating engineer requires the adaptation of light from all available sources to all purposes to which it may be applied. The available sources include both daylight and artificial light from bodies made incandescent by heat or by the application of electrical energy."

After discussing in detail the equipment and methods used by the bureau to test lamps purchased by the federal government, Dr. Lloyd gave data on life testing and federal lamp specifications. These specifications are to be issued later as Circular 13 of the Bureau of Standards. They must be complied with in the case of government purchases of multiple incandescent lamps and are available to all private purchasers who wish to follow similar specifications.

In the discussion of public utility standards, Dr. Lloyd stated that the investigation of the bureau on the subject of street lighting has been delayed by the war and probably will not be completed until after the war's termination. The bureau has recently been engaged in helping to formulate safety standards for application in federal industrial establishments such as navy yards and arsenals. Among the standards are included requirements for illumination in these establishments.

Finding Best Character of Community Rate

Discussion of the Advantages of the Method Employed by the Public Utilities Commission of Illinois in Approaching a Decision on This Matter—Tabulated Data Showing How Conclusions Were Arrived At

BY BERT H. PECK*

Electrical Engineer State Public Utilities Commission of Illinois

HAVING prepared and presented data on the value of property, the next thing with which the engineer must supply the commission in a rate case is information bearing upon the character of the rates best suited to give the revenues which may be determined upon. The methods of the State Public Utilities Commission of Illinois for handling this work are unique and offer some elements of advantage over others which may be employed.

The determination of the specific rates applicable in a given instance presents a question having two aspects: first, the question arises as to the character of rates best suited to meet the conditions prevailing in a given case; second, the question arises as to specific numerical rates of the character determined upon which will give the certain revenues desired.

The Illinois commission early realized this fact and has always endeavored to secure opinions from the utility involved, from responsible representatives of the community concerned and from its own experts as to the character of the rate which is best suited to the particular conditions that prevail. The methods by which this information may be presented to the commission were at first subjects of quandary.

PLAN ADOPTED BY THE COMMISSION

If complete testimony were taken regarding valuations and operating expenses and the commission entered a finding as to the total annual revenues to be allowed and then reopened the case for the purpose of taking testimony as to the character of rates best suited, the case would be unduly prolonged. If a finding were entered as to the revenues and a determination of the rates left with a utility, one of the principal sources of controversy would still remain. After careful consideration of this entire matter the commission determined upon the plan of instructing its engineering staff to present in the record a schedule of rates which should give a revenue of an amount which might be indicated or assumed by the engineers. This necessitates that the engineering staff shall assume a valuation of the property, shall assume a rate of return, shall assume an amount of operating expense, and based upon these assumptions compute an amount of annual revenue and develop a schedule of rates which will meet it. This results in bringing into the record a specific character of rate schedule for discussion. It possesses the disadvantage from the witness's standpoint of compelling a number of assumptions which are somewhat without the range of his jurisdiction, and in a sense results in putting his testimony up for the sole purpose of being shot at. It has, however, proved successful for the purpose for which it was intended, namely, the securing of expressions of opinion by all concerned as to the best rate to meet a given case.

The second phase of the subject in which the commission is interested—namely, the numerical determination of a specific rate which will give a certain definite revenue—necessitates the introduction of consumer data to which a given rate schedule may be applied. These data are taken from the books of the utility by the accountants of the commission, who arrange and tabulate them in such form that they are applicable for the purposes intended. The working out of these forms and tabulations presented a pioneer field, and in handling the problem the engineer and accounting staffs of the commission collaborated, with the result that a form was developed, as shown in Table I, which is taken from an actual record placed before the commission in a rate-making proceeding. The data must be tabulated in such a manner that any form of rates may be applied thereto. The commission, in working out its schedule of rates, has relied upon its engineers for a computation of revenue which a given rate will develop. A superficial consideration will indicate the impracticability of applying a given rate to a total year's bills by multiplying each bill separately, and it was therefore necessary to develop a system whereby a revenue could be rapidly computed and changes contemplated in a schedule could be readily adopted without an entire recomputation (Table II). A table of this form is applicable only to a block or step schedule of rates. If rates of the Wright demand form are contemplated, the information must be worked up in the form shown by Table III. Having obtained information in these forms, it will be seen that a given rate may be applied in a very few minutes, with the result that the commission is at liberty to alter certain phases of the rate as frequently as desired, without entailing a large amount of work in the computations of changes of revenues which are involved. In a particular case that I have in mind fully sixty rates were worked up and applied before a final schedule was determined, and the amount of time involved was not a serious consideration.

ALLOCATING OPERATING EXPENSES AND FIXED CHARGES

The revenues thus derived are, of course, revenues for a specific year's consumption, and if the commission determines that it wishes to take into consideration certain increases or decreases in consumption, these can be readily cared for by obvious methods. In this discussion of forms of rates I have not taken up the matter of allocation of property values and operating expense to the different classes of service rendered. Such different classes of service frequently comprise residence service, business lighting service, flat-rate lighting service, direct-current power service, alternating-current power service and municipal street-lighting service. These classes of service are very frequently met, and in addition there are, of course, the

*Excerpt from a paper presented before the Western Society of Engineers and the Chicago Section, A. I. E. E.

almost limitless possibilities of limited-hour service and seasonal service which may arise. The proper allocation of operating expense and fixed-charge items is a large problem and requires further analysis of operating characteristics. In a solution of this problem the engineers of the Illinois commission, in handling electric rate cases, have usually presented load curves of

the electric system obtained from station log sheets of the utility.

The methods made use of for this allocation might well form the subject of a long discussion. In addition to the allocation of the various classes of electric service, in the case of a jointly operated property there usually arises the matter of the allocation of property and expense to a water property or a street railway or heating property.

I have discussed in the foregoing the issues which usually arise and may be expected to arise in every rate investigation. In many cases other issues entirely dissimilar will arise. In a recent instance a property was under investigation, and the usual study of values and operating expenses was conducted. In making some further investigation of general conditions it was discovered that the consumptions per consumer were materially less than those which had been found in other instances, and we came to the conclusion that the consumers' meters were registering in error. An examination developed that these meters, which were of the direct-current commutator type, had been in service for many years without inspection or adjustment. Mat-

TABLE II—TABLE SHOWING THE CONSUMER-MONTHS AND KILOWATT-HOUR CONSUMPTION OF BUSINESS CONSUMERS

Kilowatt-hour Monthly Consumption per Consumer	Consumer-Months	Total Kilowatt-hours

201 and over	1,225	634,060
Total	11,945	1,060,226

ters of this nature are certainly of vital importance in a rate consideration, and it behooves the engineer conducting an investigation to be thoroughly alive to unexpected possibilities of every nature. Studies of distribution efficiencies will often disclose defects in equipment of which the utility is not aware.

INVESTIGATION DISCLOSES FAULTY METER

In another recent investigation our examination disclosed distribution efficiency of approximately 85 per cent in a community of about 1200 population. This excited our suspicion, and we made a test of the meter under which the utility procured its energy over a

TABLE III—TABLE SHOWING THE CONSUMER-MONTHS AND KILOWATT-HOUR CONSUMPTION OF BUSINESS CONSUMERS

Hours' Use of Maximum Demand	Consumer-Months	Total Kilowatt-hours
First 30 hours' use	4,074	42,210
Next 30 hours' use	2,627	82,954
Excess over 60 hours	5,244	935,062
Total	11,945	1,060,226

transmission line. This test disclosed that the meter was in error. Clearly a matter of this sort should be corrected before the rates are fixed for electric service. I mention these points as indicating the very wide scope of action and investigation which in justice should be conducted in connection with proceedings for the determination of rates.

In the course of the commission's work, which has covered several years, we early saw the need of collecting data from every source available, even though its application to the case immediately in hand was of

oubtful import. Such data collected with care and copious notes as to the conditions which prevail often-times prove invaluable in their application to other cases where the need is more apparent but where the

ulations necessary, besides broadening the possible scope of the inquiries. Data shown in Tables IV and V were prepared for two cities from the results obtained by these methods in a form which I believe may be of

STATION & OPERATING PRACTICE

A Department Devoted to Problems of Installation, Operation and Maintenance of Equipment for Economical Generation and Distribution of Electrical Energy

COAL-HANDLING METHODS IN SUBURBAN RESERVE YARD

Various Kinds of Electrical Apparatus Are Installed to Handle Coal at Minimum Cost and Greatest Efficiency

The United Electric Light Company of Springfield, Mass., maintains a reserve coal supply in a field recently equipped for this service at Indian Orchard, about 6 miles (9.7 km.) from its principal generating station. The storage capacity is about 50,000 tons, but as shown in the accompanying illustration, taken recently, the supply of coal has been heavily reduced by the stress of winter weather and the shortage of fuel common to the entire East. Coal is brought to the reserve field by rail, and the trackage facilities include

HOW RAILROAD AND COAL-GATHERING TRACKS ARE RELATED TO COAL PILES

a siding 320 ft. (97.5 m.) long for temporary car storage, a discharge and loading track about 406 ft. (123.7 m.) long running through the storage area from east to west, and a 405-ft. (123.4-m.) section of standard-gage track without connection to the remaining rails, upon which is operated an electric locomotive crane.

The tracks are in general supported on reinforced-concrete walls or a trestle. The trestle was designed for Cooper's E-60 loading, corresponding to heavy main-line service. The crane, which was built by the Industrial Iron Works, Bay City, Mich., has a rating of 6100 lb. (2766.9 kg.) at a radius of 45 ft. (13.7 m.). It is operated by a 75-hp. Westinghouse three-wire, two-phase, 440-volt induction motor of the variable-speed type. Resistors for this service are mounted in the cab and are wired in conduit to Cutler-Hammer control equipment of the solenoid type mounted on a switch-board in one corner. Crouse-Hinds condulets are used, and the wiring is unusually rugged and well laid out for the service. The motor-control cylinder can be rotated mechanically by levers and either of two handles at the right and left sides of the operator's stand.

Energy is supplied to the field from the company's Indian Orchard generating plant and substation, close by. The locomotive receives energy through a jumper cable plugged into any of seven jack boxes mounted on a guard pipe-rail run along the side of the trestle track. These boxes are also of Crouse-Hinds design, and each is fused by a 100-amp. fuse block set carried in a box designed by the Chicago Fuse Manufacturing Company. No loose wiring is employed, barring the flexible cable feeding the locomotive from the jack box. The jack boxes are held in place against the guard railing by 2-in. by 5/16-in. (5-cm. by 0.8-cm.) iron straps, and the rail is of 1.5-in. (3.8-cm.) pipe throughout.

Except under the most extreme conditions coal is transported to the city station of the United company by railroad cars loaded from the reserve pile by the locomotive crane, but last winter it was necessary for a time to haul this fuel by gasoline motor trucks. The crane is operated by an employee of the company ordinarily at the State Street station in Springfield, the Indian Orchard plant being a hydroelectric generating station only. The yard and its fixed facilities were designed by McClintock & Craig, engineers, of Springfield, Mass.

DETERMINING THE SIZE OF WATT-HOUR METER

Considerations That Should Be Taken Account of in Connection with Customers' Installations to Further Economy and Accuracy

According to a discussion on meters at the recent convention of the Minnesota Electrical Association, there is a very decided tendency toward the installation of meters of smaller sizes. Where there is any question about the size of meter to install some central-station companies are using small-size meters, leaving it to the new-business department to obtain as large a load as it can. This practice has led to practically no trouble. In Minneapolis 95 per cent of the meters installed are of the 5-amp. type. Even for electric ranges, meters of the 15-amp. variety are used there. It is never desirable to install a meter of higher rating than is necessary to register the load efficiently and economically. Putting in too large a meter not only increases the investment in meters but also results in a large loss of revenue owing to light-load inaccuracy.

In general, when installing a meter the class of service must be considered. What applies to one customer does not necessarily apply to another. For example, in churches, stores, lodge halls, saloons, etc., the total connected load is nearly always used and a meter rated at 80 per cent of that load should be installed. For electric signs and like loads meters rated for the total connected load should be installed. In residences only

a few lamps are used at one time, as a general rule, and they are usually not of large size. Occasionally during some special functions the total connected load will be used. At such times a small meter would have to carry considerable overload. However, most of the modern meters will carry 200 to 300 per cent overload without danger of damage to the meter and will carry 400 per cent for a few minutes. The meter will operate slow on overload owing to the fact that the series-coil laminations are oversaturated. However, the infrequent loss resulting from overload will be compensated for by the increased activity of the meter on small loads of one or two lamps. Hence it is always advisable to install a meter having a rating equal to 25 per cent to 50 per cent of the total load in a residence.

The same rule also applies to power customers having many small motors or one large motor. It is always advisable to install a meter with 60 per cent to 75 per cent of the rating of small individual drives and 75 per cent to 100 per cent for a large single motor. Experience has proved that this is the best practice except with motors operating elevators and cranes which are started and stopped frequently. These motors draw large starting current, so the best practice is to use a meter with 100 per cent to 125 per cent of the rating of the connected load.

Save Liberty for the World

CONVENIENT MOUNTING FOR REGULATOR ACCESSORIES

Current Transformers and Other Appurtenances
Supported on Panels Which Are
Attached to Regulators

Instead of mounting the current transformers and other appurtenances used in conjunction with voltage regulators in the usual manner, one of the Southern companies has employed the arrangement shown here-

PANELS ATTACHED TO REGULATOR CASES

with. The accessories are mounted on panels attached to the top of the regulators principally because there was no room for panels in front of or at the side of the regulators. However, this arrangement has most of the advantages of the usual method and besides saves some wiring.

BRACING LINE TOWER

Ordinary Straight-Away Tower Reinforced to Avoid Buying Angle Tower

By means of attaching a latticed structure to an ordinary straight-away line tower and then guying it

at right angles to the line a company in New England was able to use a standard tower where an angle tower would ordinarily have been required. By so doing it avoided buying a special tower which would have been more expensive than the structure used. As will be seen, a branch line is attached to the tower at right angles to the through line at this point. This arrangement has proved perfectly satisfactory from a structural point of view, and in these

days of compulsory economy it has, as will readily be seen, much to recommend it.

PREVAILING TREND IN GROUNDING PRACTICE

Discussion of Types of Ground Connections and Factors That Enter Into Establishing a Reliable
Connection with the Ground

The characteristics of different types of ground connections and the field to which each type is fitted for use were discussed by W. C. Wagner, electrical engineer of the Bureau of Standards, in a paper presented before a recent meeting of the Western Association of Electrical Inspectors. He also explained why the weather conditions and soil surrounding the ground connections are important factors. The methods of grounding in common use are driven pipes, plates, strips, water pipes and patented devices.

The driven-pipe ground connection is economical and reasonably satisfactory for lightning protection grounds and low-voltage circuits when high-potential and low-potential conductors are not likely to cross and when the resistance is not required to be less than a few ohms. Driven pipes are easily inspected, readily removed and do not require large ground areas.

The latter advantage is important in places where the ground must be installed in restricted space or under pavements. Mr. Wagner said: "A greater depth of penetration than 10 ft. (3 m.) in conducting soil is not, in general, economically advisable. An earth connection to be efficient must be below the frost line, because a variation in resistivity of more than 200 per cent may be expected in reducing the temperature from 20 deg. C. to -20 deg. C. Several driven pipes connected in parallel decrease the resistance of the ground connection when the pipes are separated from 1 ft. to 8 ft. (0.3 m. to 1.8 m.). A pipe ground should not be made near a pole because the pole exerts a shielding

effect and shuts off a large part of the current flow. Mechanical considerations will usually govern the choice of size of driven pipe, but it has been found that the best results can be obtained with pipe from 0.75 in. (19.1 mm.) to 2 in. (5.08 cm.) in diameter."

Buried plates are not used to any extent because the driven pipe grounds are more convenient and give the same results in most cases. The area of a single plate in ordinary conducting soil cannot be economically increased beyond 20 sq. ft. (1.8 sq. m.) and should not be buried deeper than 8 ft. (2.4 m.). It is usually better to bury two smaller plates some distance apart and connect them by a wire than to bury a larger plate of the same ground resistance. The surrounding soil greatly affects the use of buried plates, and an increase of conduction can be obtained by surrounding the electrode with salt or a bed of coke. Moisture changes do not affect a coke bed, because the coke bed constitutes virtually an extension of the electrode. Coke has the disadvantage as compared with salt of requiring excavation, as the latter can be carried into the ground by moisture from a pocket at the surface. Coke also exerts a corrosive action where iron is used and is generally considered more detrimental than salt. Copper electrodes should be used where long life and minimum attention is desired. Strips should be used where bed-rock is near the surface of the ground and it is impracticable to embed pipes or plates deep enough to provide an effective earth connection. This is especially true in soil of high resistivity because of the electrostatic capacity in the case of a strip is greatest for a given amount of metal. This method is also applicable, therefore, for use in high-resistance soil where driven pipes would be used.

Water pipes give less resistance to ground than any other of the methods discussed. "A water pipe in an average soil," Mr. Wagner said, "has approximately the resistance of from fifty to sixty driven pipes or buried plates in parallel. Pipe systems are easily accessible at the service entrance. Moreover, the areas covered by electric lighting systems are approximately the same as those covered by water mains. This method of grounding is therefore advantageous and in the case of low-voltage alternating-current circuits does not appreciably affect the water-piping systems."

In the discussion patented devices were grouped under one head and were not reviewed as to their reliability.

Safety First—Buy Liberty Bonds

ACTUAL CONSTRUCTION COST OF MEDIUM-SIZE STATION

Data Refer to a 4500-Kw. Plant—The Advance in Prices Since 1916 Is Not Shown by the Figures Reproduced

In the following table is given the itemized cost of construction of a Massachusetts central station situated on tidewater and including a building designed for one 500-kw. and two 2000-kw. turbo-alternators. Construction was begun in April, 1916, and the cost of the plant, including land and preliminary engineering, built to a capacity of 2500 kw. installed machinery (one 500-kw. and one 2000-kw. unit), and covering a building, boiler, coal-handling and piping installation adequate

for 4500 kw., approximates \$269,000. It is expected that the second 2000-kw. unit will add about \$40,000 to the station cost, making the probable complete cost of the 4500-kw. installation about \$309,000.

PUBLIC POLICY MESSAGES ON CUSTOMERS' STATEMENTS

Oregon Property Takes Up Each Month a Different Phase of the Relations Existing Between Utility and Public

The North Coast Power Company, Hillsboro, Ore., has inaugurated the policy of submitting to its customers with each monthly statement a public policy

Prompt Payments

All bills by the North Coast Power Company, due and payable the first of each month, are for services rendered the preceding month. Bills not paid by the 10th of the month become delinquent and the service subject to discontinuation without further notice.

It is necessary, in fact, required by state law, that public service utilities adopt definite rules and regulations pertaining to their service, and to observe a uniform system of rates and methods of collection.

The above rule is as necessary to the efficient and economic operation of the North Coast Power Company properties as is the continuous and reliable service given. It is as necessary as the personal service and industry of its employees. The accurate accounting and keeping of the many individual records require its enforcement.

Time wasted in carrying delinquent accounts and lost in enforcing their collection would otherwise be devoted to improve the service, to decrease the operating expense, and ultimately to reduce the cost of service to the consumers. Kindly keep these facts in mind and make remittances promptly.

"story" in which a definite phase of the relation existing between the utility and the public is analyzed.

War Savings Stamps

21,000,000,000 dollars!

This amount Congress appropriated the past year to carry out the great war of Democracy and Humanity.

From the birth of our country's freedom in 1776 to 1917, 141 years, the cost of operating its government has been 26,000,000,000 dollars. This sum includes all wars in that period.

Now, in less than a year, this World War of Freedom has caused our government to raise a sum almost as great as that which maintained our country's freedom nearly a century and a half.

2,000,000,000 dollars of this amount is to be in small sums, chiefly twenty-five-cent pieces. The annual saving of each American citizen is but \$50. It is evident that a great number have been unable to subscribe to Liberty Loan issues. To offer these people a chance to do their bit the government is issuing War Savings Stamps. 100,000,000 people in the United States to raise 2,000,000,000 dollars means \$20 per person—means 4 War Savings Stamps or 80 Thrift Stamps to each man, woman or child.

Don't fall below the average!

Sacrifice something !

Save something!

Be loyal, unselfish!

Help win the war!

The North Coast Power Company sells War Savings Stamps.

PUBLIC POLICY SERIES NO. 1

NORTH COAST POWER CO.

A Tri-Cornered Proposition

The public utility exists by reason of a need for the service for which it was created to render. This service is successfully and economically given only when the three prime factors entering therein, the investors, the operators and the public, each provides an adequate service at a fair return. No contract or agreement survives which does not provide a mutual aid and just transaction to all parties concerned.

The investors' need must provide sufficient funds to construct the skeleton around which the utility is to grow and to provide for its future extensions. Their return is a fair interest on the amount invested.

The operators provide the sinews by means of which the plant moves—becomes a growing concern. The employees, by reason of systematic methods, industry, loyalty and efficiency, produce reliable service at economic rates. Fair wages and humanitarian treatment attract and hold such employees.

The consumer provides the protoplasm by means of which the utility grows and prospers. A sick or impoverished horse plows a poor furrow. A constantly criticised employee fails to perform his duties properly. The public best serves itself by protecting the utility from unjust criticism and abuse and by eliminating unfair restrictions which tend to cramp the growth of the utility. Its fair return is reliable service at lowest possible rates which tend to upbuild the community, invite further investment of capital and maintain stable business conditions in general.

THE INCREASED COST OF LINE EXTENSIONS

Chicago Companies Point Out Comparative Cost of Construction Under Present Conditions and Under Conditions and Prices in 1914

In testimony before the State Public Utilities Commission of Illinois, A. S. B. Cushing, statistician of the Public Service Company of Northern Illinois, presented figures to show how the cost of constructing service extensions has increased since the beginning of the great war. The data which he presented apply to the company's system, which supplies approximately 170 villages, cities and communities. Its lines extend over a territory of approximately 5000 square miles (1,295,000 hectares) in which there is a population of about 500,000. This system is supplied from eighteen plants, of which only eight are of importance.

In regard to the study of the investment in a two-pole line extension Mr. Cushing said: "First, we have a certain amount of copper wire and two 35-ft. (10.6-m.) poles, the expense of shaving and painting the poles, labor for delivering and setting the poles, the usual cross-arms, insulators, braces and other hardware, and then the labor of putting up the braces, putting up the cross-arms and stringing the wire, the present total cost of such items being \$77.40. To this amount we must add 10 per cent of the material cost for storeroom charges on the items which pass through our storeroom stock. This adds another \$5.49. Then 5 per cent of the \$77.40 must be added for drafting expense and general records. Another 5 per cent must be added for engineering and incidentals, which brings a total of \$90.63.

"Now, in a great portion of the company's territory the various telephone companies join in the investment for poles, and I have used in my calculations 35-ft. poles, because 35-ft. poles are required when the telephone company joins in the investment. Therefore I have subtracted from the aforesaid \$90.63 a half interest in the poles, and that half interest is figured at \$9 per pole. I have thus subtracted \$18, leaving the net cost for a two-pole extension \$72.63. This is the cost of such an extension with present prices.

"To this amount must be added," continued the speaker, "the customer's share of transformer capacity. That for a residential customer in the Public Service Company of Northern Illinois would average at the present time approximately \$5.25. There would also have to be provided a service drop that averages 189 ft. (57.6 m.) of No. 8 double-braided weatherproof copper wire at a present cost of \$12.68. Also, the weighted average cost of an electric meter for a residential customer at present costs would amount to \$8.51. All of such items would have to be added to the \$72.63, making a total of \$99.07. These items are all charged to the capital account."

For normal prices Mr. Cushing took the figures for

the year 1914, as prices at that time did not seem to have been affected by war conditions. The cost of a two-pole extension in those normal times was \$44.07 for a residential customer, as compared with \$72.63, an increase of about 70 per cent. The cost of transformer capacity per customer in normal times was \$3.55, as compared with the present cost of \$5.25, or an increase of approximately 48 per cent for the present time. The cost of a service drop in normal times was \$6.99, as compared with the present cost of \$12.68, making the present cost an increase of 81 per cent over normal-time prices. The cost of an electric meter in normal times was \$7.16, as compared with \$8.61 for the present time, making the present cost about 19 per cent more than in normal times.

Mr. Cushing stated that the total cost of line extensions of his company during the year 1916 was \$650,629.05. During that year the company issued approximately 5000 work orders for all line work, of which it was estimated 1500 were for two-pole line extensions. It was also brought out that about 92 per cent of the total two-pole extensions were for residences, the other 8 per cent being for commercial houses or factories.

Homer E. Niesz, assistant to the vice-president of the Commonwealth Edison Company, in the same case stated that the present cost of a two-pole line extension on the lines of the Commonwealth Edison Company is between \$75 and \$80, and that the cost of a two-pole line extension in 1914 was approximately \$50. These were average costs.

MAKING USE OF STICKERS TO HELP WITH COLLECTIONS

A Series That Are Used by an Eastern Lighting Company and Have Produced Favorable Results Show Individuality

The accompanying series of stickers are used by the Kingston (N. Y.) Gas & Electric Company in connection with its collections and have had good results.

WE believe this account has been overlooked and take this means of reminding you that same is due and trust you will remit promptly. No. 1

THIS account is small and has no doubt been overlooked by you. To save us sending you notice again kindly remit at once. No. 2

WE respectfully call your attention to this overdue account courteously asking you for a substantial payment by return mail. No. 3

PLEASE give this account your immediate attention. It is long past due so we must ask you for settlement promptly. No. 4

WE have repeatedly called your attention to this account and unless paid at once we will take other steps to collect. No. 5

THANK YOU!

STICKERS USED BY NEW
YORK STATE LIGHTING
COMPANY

Such stickers lend individuality to the account. They are courteous yet firm.

The series is numbered, and different-colored papers help to distinguish the different numbers.

EFFECT OF DAYLIGHT SAVING

Load Curve of Residential Feeder Shows that Peak, Besides Being Shifted, Has Been Lessened

A decided shift in peak load accompanied by a reduction of the demand is shown in the accompanying curves taken on one of the residential lighting feeders of the Hartford (Conn.) Electric Light Company on the Sunday preceding the inauguration of daylight saving and the first day under the new program. The evening peak on March 24 occurred about 7 o'clock, while that of Easter Sunday was at 8 p. m., with a reduction of about 16 per cent. From 9 o'clock on the loads on the two days were almost coincident. On the morning of each day the conditions were reversed, the peak load (not shown on the diagram) reaching 30

HOW DAYLIGHT SAVING AFFECTS RESIDENTIAL LIGHTING

amp. on two phases of the circuit on the 31st, compared with a morning peak of 21 amp. on the 24th. The reduction in the evening peak following the institution of daylight saving is significant in view of the importance of keeping the investment down for this class of business.

NINETY PER CENT COLLECTIONS BY TWENTIETH OF EACH MONTH

Indiana Company with 1 Cent per Kilowatt-hour Discount Delivers Card Bill and Mails but One Delinquent Notice

Since the increase in postage the Indiana Railway & Light Company has been delivering the monthly bills to its 6000 creditors in Kokomo on the first of the month by meter readers at a cost of approximately \$35 per month, or, roughly, half a cent per bill. Bills are in card form, as illustrated, the cards measuring 3¼ in. by 5½ in. (8.25 cm. by 14 cm.). The back of the card is used for timely advertisements. A discount of

1 cent per kilowatt-hour is allowed for payment before the tenth, and it is noticed that approximately 80 per cent of accounts take advantage of this. On the twenty

No. _____ 191

M _____

As the bill presented for electricity on _____ 191, amounting to \$ _____ may have been lost in transit, mislaid or perhaps forgotten, we take the liberty of reminding you that the ten-day limit will expire _____ 191, at 12 o'clock, noon, after which date service will be discontinued without further notice.

A charge of \$1.00 is made for re-connecting.

Respectfully,
INDIANA RAILWAYS AND LIGHT CO.

Our consumers will save at least one month's lighting bill in the course of a year if they will take advantage of the discounts given by paying on or before the last day of the discount period.

DELINQUENCY NOTICE MAILED TO TARDY CUSTOMERS

of month following period energy was used; additional 10 per cent by twentieth of same month; additional 9 per cent by twentieth of following month—leaving approximately 1 per cent for disconnection delinquents.

TECHNICAL THEORY & PRACTICE

Including a Digest of Important Articles Appearing in
the Scientific and Engineering Press
of the World

Generators, Motors and Transformers

Unique Three-Phase Transformer Connections.—The banking of transformers for different load conditions is discussed and illustrated.—*Power Plant Engineering*, April 1, 1918.

Materials and Their Arrangement in Transformer Construction.—Factors that influence the selection of conductors for primary and secondary windings, iron for the magnetic circuit and insulation for both of the foregoing are dealt with in the article.—*London Electrician*, March 22, 1918.

Notes on the Design of Electromagnetic Machines, Part II.—STANLEY PARKER SMITH.—A three-phase turbo-alternator is designed to give 2000 kw. at 3000 r.p.m. at a line pressure of 500 volts, and the mechanical stresses in the rotor are discussed.—*London Electrician*, March 15, 1918.

Lamps and Lighting

Recent Developments in Marine Lighting.—Illuminants, unattended lights and types of flashers, etc., are described.—*London Engineer*, March 8, 1918.

Survey of Methods of Directing and Concentrating Light.—LIEUT.-COMMANDER HAYDN T. HARRISON.—From two well-known laws the author concludes: (1) that with beams that are approximately parallel it can still be considered that the illumination is inversely proportional to the square of the distance from the source, provided that the illumination is measured at sufficient distance to eliminate any error due to the area of the secondary source or mirror; (2) that the luminous flux from a parabolic mirror, if focused so that there is little dispersion, is proportionate to the square of its area divided by the square of the area of the source. Included in the article is a table which gives the luminous value obtained by the concentration of light at angles of 270 deg., 180 deg. and 90 deg., being the equivalent of deep, medium and shallow reflectors. Such luminous value is calculated by dividing the solid angle of luminous flux by the solid angle of the beam produced.—*London Electrician*, March 8, 1918.

Generation, Transmission and Distribution

Control of Large Amounts of Power.—E. B. WEDMORE.—The increasing use of electrical energy and its economical production require the use of larger generating stations and the linking together of existing plants. These extensions involve something more than the use of larger units and the adding of unit to unit. The several factors that determine the new conditions are discussed in detail.—*London Electrical Review*, March 15, 1918.

Availability of Energy for Heat and Power.—JOHN BLIZZARD.—The article outlines the sources from which Canada receives supplies of energy and the extent to which each is utilized. In the course of a year Canada

burns 30,000,000 tons of coal, of which 60 per cent comes from the United States, the remainder being mined in Canada. Six million tons are used for industrial power. Water power is used for the most part to supply mechanical and electrical energy. About 2,000,000 hp. has so far been developed. The total available horsepower is estimated at about 18,000,000 hp., of which 8,000,000 hp. is estimated to be available within the present range of markets. An additional development of 6,000,000 hp., assuming an efficiency of conversion of 60 per cent and a plant factor of 40 per cent, would supply about 1,500,000 hp. continuously. This is much more than sufficient to supplant that generated yearly by 16,000,000 tons of coal. Different types of central stations are then considered: (a) Those in which the fuel is completely gasified by partial combustion and the energy distributed either as gas or electrical power; (b) those in which the fuel is carbonized and energy distributed in the form of solid fuel and gas or electricity; (c) those in which the fuel is completely burned and electrical energy and steam distributed; (d) those in which fuel is completely burned and electrical energy only distributed.—*Toronto Electrical News*, March 15, 1918.

Cables and Ocean Beds.—The problems that have to be met and the methods of solving them in the laying of submarine cables are discussed.—*Telegraph and Telephone Age*, April 1, 1918.

Outdoor Switching Apparatus.—H. G. MACDONALD.—The increase in distance covered by electric power transmission lines and the corresponding increases in voltages to make such transmission lines practicable are discussed and reference made to outdoor equipment which is suitable for this service.—*Electric Journal*, April, 1918.

Hydroelectric Industry in Scandinavia and in the Dutch East Indies.—(Abstract from a lecture given by A. Groothoff before the Royal Institute of Engineers in Holland.) The useful water power of Norway is estimated at 7,000,000 hp., of which the state owns by purchase one-seventh and utilizes about 1,000,000 hp. Sweden has about 6,000,000 hp., of which the state owns one-sixth and utilizes about 1,000,000 hp. While Norway's water power is fairly divided over the entire country, Sweden's is concentrated in the bleak, sparsely inhabited northern portion. The generating station at Nove transmits 210,000 kw. over 125 km. at a pressure of 110,000 volts. The cost of the entire station and system was \$3,000,000 and the cost of a kilowatt-year around \$1.50. During 1916 approximately half of the energy supplied by the state works of Sweden was utilized by the electrochemical industry.

Traction

New Type of Power Transmission for Berlin Railways.—Instead of using overhead wires or "third-rails," the engineers are planning to run high-tension

wires near the "inside" rail. Instead of scrapping the entire car equipment, the management has decided to build only trucks and to attach the old cars to the new electric trucks.—Abstracted in *Schweizerische Bauzeitung*, March 2, 1918, from an article in *Zeitschrift der Verein d. E. V.*

Gearless Locomotive for the St. Paul.—A. H. ARMSTRONG.—The article deals with the extreme simplicity in design offered by mounting the armature directly upon the driving axle, thus eliminating all gears, quills, jack shafts, side rods, etc. The article gives detailed information in connection with the 3000-volt gearless locomotive now under construction in the General Electric shops for the Chicago, Milwaukee & St. Paul Railway's extension to Seattle.—*Electric Railway Journal*, March 23, 1918.

Installations, Systems and Appliances

Industrial Controllers.—H. D. JAMES.—This article, which is the sixteenth installment of a series, includes various illustrations showing methods of connecting motors and controllers for industrial applications.—*Electric Journal*, April, 1918.

Discussion by the Faraday Society on Electric Furnaces.—The distribution of the heat in electric furnaces is discussed.—*London Electrician*, March 15, 1918.

The First Electric Steel-Melting Furnace in South Africa.—W. BUCHANAN and GEORGE H. STANLEY.—The author deals rather exhaustively with the subject of the quasi-arc process and embodies information of value related especially to electric steel-melting furnaces.—*Transactions of the South African Institute of Electrical Engineers*, November, 1917.

Wires, Wiring and Conduits

High-Voltage Condenser for Radio Transmitters.—Description of a type of high-voltage condenser which is said to have sufficient dielectric strength under the strain of the impressed voltage of the average wireless transmitter to prevent break-down. Another important feature of the condenser is that it is equally applicable to high and low voltages and may be used in radio-frequency circuits of a wireless-telegraph transmitter or for measurements in an experimental laboratory.—*Wireless Age*, March, 1918.

Electrophysics and Magnetism

Direct-Current Corona.—SYLVAN J. CROOKER.—The influence of series sparks on direct-current corona is discussed and the results of experiments are recorded. It was observed that a spark gap in series with the discharge tube affects the positive and negative corona in very characteristic and striking ways. The changes are due to intermittent currents. A hot-lime-cathode Braun tube was developed and used in observing the weak pulsating currents which pass through the spark and the corona tube. Evidence was given to show the relation of the corona to the arc discharge. An attempt at an explanation of the pulsating current has been made.—*American Journal of Science*, April, 1918.

Electrochemistry and Batteries

Processes for the Manufacture of Aluminum.—Alumina (Al_2O_3) in a bath of molten cryolite is subjected to electrolysis and yields metallic aluminum and free oxygen which burns the carbon electrode to form carbon monoxide, the latter in turn yielding carbon

dioxide. The supply of electrical energy which is used to effect electrolysis is also used to keep molten the salts, but since the consumption of energy necessary for the double purpose is excessive, the process can be used commercially only where very cheap energy is available. The chief phases of the complete manufacturing process are discussed.—*London Electrical Review*, March 8, 1918.

Units, Measurements and Instruments

Great Britain's Interest in the Metric System of Weights and Measures.—HARRY ALLCOCK.—The author compares the conditions in Germany and Great Britain with regard to the employment of the metric system, pointing out that the longer the adoption of this inevitable reform is referred the greater will be the magnitude and extent of the incidental difficulties to be overcome.—*London Electrical Review*, March 1, 1918.

Telegraphy, Telephony and Signals

Signaling and Interlocking of Keadby Railway and Bridge.—JAMES BENJAMIN BALL.—The article deals with interlocking and signaling as applied to the railway and bridge and also with certain safety and protective devices which were utilized.—*London Engineering*, March 1, 1918.

The Effects Produced Upon Audion Characteristic Curves by Various Kinds of Signals.—A. D. COLE.—The buzzer, electron relay and 60-cycle alternating current have been investigated to find out to what extent the magnitude of the plate and grid signals is influenced by the kind of excitation applied. It was found they produced different effects, which were embodied in curves involving plate current, grid current and grid signal. The experiments were conducted at the United States naval radio laboratory. The work is being continued at the Ohio State University.

Radio Inductive Interference.—LIEUT. ELLERY W. STONE.—The inductive interference from radio stations on telephone lines is discussed.—*Telephony*, March 30, 1918.

Miscellaneous

Nomenclature.—A. P. TROTTER.—A discussion of the electrotechnical terms in use in the English language as decided upon by the British national committee of the International Electrotechnical Commission is set forth.—*London Electrical Review*, March 22, 1918.

Engineering Evolution of Power Plant Apparatus, Section 27.—FRANCIS HODGKINSON.—Reviewing steam turbine development, this continued article deals with lubricating systems, exhaust passages, progress and future possibilities, etc. Performance curves are included.—*Electric Journal*, April, 1918.

Rusting of Boiler Tubes and Its Prevention.—BRUNO ZSCHOKKE.—The results of exhaustive tests indicate that there are five causes which produce rusting and corrosion of boiler tubes, viz., (1) acidity of feed water, (2) formation of detrimental quantities of free hydrochloric acid, (3) formation of fatty acids, (4) localized electrolysis effects, (5) chemical change due to the combination of water with the iron. Among the preventive means suggested are 0.05-0.10 per cent chrome-salt (bichromate-of-potassium) solutions, which show remarkable rust-preventing properties. Sodium bichromate would be just as effective and much cheaper for practical use.—*Schweizerische Bauzeitung*, March 2 and 9, 1918.

Scientific and Industrial Research

A Department Devoted to Interchange of Ideas, Investigations Contemplated, Research Facilities Available, and Suggestions for Co-operative Work.

Conducted by PROF. VLADIMIR KARAPETOFF

Cornell University, Ithaca, N. Y.

Investigations Under Way or Completed

(RESEARCH WORK REPORTED SINCE MARCH 16)*

AUDION CHARACTERISTICS.

Experiments are being conducted on the effect upon the audion of various kinds of signals, namely, buzzer, electron relay and 60-cycle alternating current. Three audions have been examined to find out how much the magnitude of the plate signal and of the grid signal depends upon the kind of excitation used. It was found that the magnitude of the effect, its law of change with variation of direct voltage on the grid, and even its sign, were different according to whether the signal emf. was produced by a buzzer, an oscillating audion or a 60-cycle alternating-current source.—A. D. Cole, Ohio State University, Columbus, Ohio.

CABLES, HEATING OF.

Experiments show that the maximum safe working internal temperature of an 11,000-volt cable is 150 deg. Fahr. By placing blowers in alternate manholes and forcing the hot air out of the ducts through the intervening manholes it was possible to reduce the duct temperature about 40 deg. Fahr. in one section containing heavily loaded cables.—W. A. Keating and C. H. Mueller, Duquesne Light Company, Pittsburgh, Pa.

Crude vaseline when used as a filler to replace the air in duct lines reduces the heating of a cable to a considerable degree, with the following advantages: (1) increased current-carrying capacity, (2) elimination of hot spots, (3) decreased electrolysis, and (4) mechanical protection. Dissipation of heat from cables now in service is limited by the high internal heat resistance in the cables themselves. Removal of heat by crude vaseline is practical commercially, as far as can be determined by laboratory test. It is recommended that the next step be a trial in some actual line duct.—E. O. Schweitzer, Commonwealth Edison Company, Chicago.

CABLES, VACUUM FORMATION.

Several breakdowns have occurred a few feet from splices, suggesting that a partial vacuum may have been formed there at low temperatures and that moisture was subsequently sucked into the insulation. A whistling sound has actually been reported by the workers after the removal of sealing caps in cold weather. Experiments have shown that if the pressure within a cable is atmospheric at say 90 deg. Fahr. an underpressure as high as 1.6 lb. per square inch (112.5 gm. per sq. cm.) may be developed at 32 deg. Fahr. Research is therefore desired to develop a method of splicing at a low temperature to prevent this suction of moist air when the cap is removed.—William A. Keating, Duquesne Light Company, Pittsburgh, Pa.

CONDENSERS, PRE-CHARGED.

A theoretical investigation of the properties of electrostatic condensers in series and in parallel, the condensers assumed to be pre-charged to different voltages before being connected into circuit. The theory as developed explains and generalizes the performance of the so-called Delon apparatus recently proposed in Europe for testing cables with high-tension direct current.—V. Karapetoff, Cornell University, Ithaca, N. Y.

CORE LOSSES IN MOTORS.

Iron losses in single-phase and polyphase motors have been studied. A two-phase motor having two complete single-phase pyramidal windings was tested and the losses carefully analyzed when operated on both two-phase and single-phase. The flux densities were the same for single-phase and for two-phase operation. The results show that the total iron losses were also substantially the same in both cases. There is a theory regarding single-phase motors according to which the motor has a double-frequency current in the armature when it is running at synchronous speed. This might lead one to think that there should be iron losses in the rotor of the single-phase motor when operating at or near synchronous speed. The above results, however, show conclusively that there are practically no iron losses in the rotor of a single-phase motor near synchronous speed.—J. L. Hamilton, St. Louis, Mo. [The writer probably has in mind the resolution of the pulsating magnetic field into two revolving fields of opposite rotation. The flux which glides against the rotor is wiped out by the secondary currents, and this probably accounts for the absence of iron loss in the rotor at synchronism.—Editor's Note.]

HIGH-VOLTAGE MEASUREMENTS.

Corona voltmeter constants are being determined from the measurement of the voltage in the high-tension circuit. A method has been devised which involves the use of a large air condenser of accurate construction and also of a kenotron rectifying tube, so that the values of alternating voltage may be measured by a direct-current method which permits a high degree of accuracy.—J. B. Whitehead, Johns Hopkins University, Baltimore.

INDUCTION MACHINES, TORQUE.

The effect of higher harmonics on the torque of induction motors is being investigated. The subject is of special importance in connection with large two-speed motors, for if the winding is connected for half speed the winding pitch becomes favorable for the development of higher harmonics in the gliding mmf. Some of these harmonics revolve against the direction of

the fundamental mmf., causing the machine to start at a poor torque, and occasionally to stick at any intermediate speed.—Alexander Gray, Cornell University, Ithaca, N. Y.

IRON ALLOYS, COBALT.

The effect of cobalt on the magnetic and other properties of iron alloys is being studied. Specimens of alloys have been prepared with percentages of cobalt ranging from small traces up to the maximum per cent that gives a workable alloy. We hope to have the results of this investigation ready for publication before the close of the present school year.—E. B. Paine, University of Illinois, Urbana, Ill.

OSCILLATIONS, INTEGRAPH FOR REPRESENTING.

Prof. E. Pascal of the University of Naples, Italy, has built several planimeter devices which graphically integrate linear differential equations of the first and second order. The device which integrates the first order equation is applicable to electric transient phenomena which involve resistances and inductances only, with any irregular applied variable voltage. When capacity is present the differential equation of oscillations is of the second order. It is very desirable to develop further Pascal's integraph so as to make its application easy to electrical problems. In the present form the device is suitable for cases when the resistance is so high that the current is aperiodic. An improved device would be extremely useful in the analysis of transmission line oscillations and in the study of some radio phenomena. For information relating to the above see Ernesto Pascal, "I Miei Integrati per Equazioni Differenziali," Naples, 1914, and A. Galle, "Mathematische Instrumente" (Teubner), 1912, p. 161. Several articles by Pascal have appeared since 1909 in the *Proceedings of the Accademia dei Lincei*. The paper on the second order equations is dated March 19, 1916.—Editorial Suggestion.

TRANSFORMERS FOR SERIES LAMPS.

Transformers designed to operate series incandescent street lamps are being studied to determine the variations in current resulting from abnormal conditions of the circuit, such as grounded lines, broken lamps, etc.—E. B. Paine, University of Illinois, Urbana, Ill.

VENTILATION OF ELECTRICAL MACHINERY.

Data on the pressure drop of air flowing through irregular passages are being obtained and collected; a simple method has been devised for measuring air velocities. The laws of heat transfer are being investigated both within the machine materials and from their surfaces to the cooling air. The specific purpose of the investigation is to enable the designer of an induction motor to predetermine accurately its temperature rise.—A. D. Moore, University of Michigan, Ann Arbor, Mich.

Suggestions for Research

LIGHTNING.

A miniature laboratory arrangement imitating a charged cloud and a transmission line, to study the effects of direct and indirect lightning strokes.—Editorial Suggestion.

MEASURING INSTRUMENTS.

An integrating kilovolt-ampere meter for measuring total apparent input. (Under some conditions, especially at low power factor, it is more equitable to charge a customer on the kva. basis than on the kw. basis. In a more general case the charge for service should consist of at least three parts, one proportional to the real input, one to the apparent input and one to the maximum demand. A kilovolt-ampere-hour meter would be serviceable in many cases in inducing the customer to maintain a high power factor, if for no other purpose.)

MINING APPLICATIONS OF ELECTRICITY.

Further development of explosion-proof motors for coal mines; suppression of arcing in mine-locomotive controllers; electrically operated reciprocating drill; self-contained portable electric lamp for miners and wider use of electricity in cutting coal and in other operations.—A. I. E. E. Committee on the Use of Electricity in Mines.

OSCILLATION PERIOD OF COILS.

Collection of data, mathematical or experimental, on the oscillation periods of inductance coils for use in radio apparatus. Some general conclusions should be made as to the variation of the periods of coils with changes in diameter, length, number of coils, etc.—Louis Cohen, Washington, D. C.

RESONANCE TRANSFORMER.

Solution for the differential equation of a resonance transformer such as is used in radio-work, with the electric spark included. The variable resistance of the spark is a function of the instantaneous current, time and possibly of other factors. Some simple function of this resistance should be assumed and substituted in the differential equation.—Louis Cohen, Washington, D. C.

TIE-LINE PROBLEM.

The following problem is of interest to operating companies, and it is desired to obtain a solution, analytical, graphical or combined, in such a form that even one not well versed in the intricacies of alternating-current vectors or complex quantities could apply it to his own case. Referring to the accompanying diagram, two substations are fed each with polyphase power from a station bus through one or more lines in parallel. The combined impedance of the feeders to substation No. 1 is Z_a , of those to No. 2 is Z_b . The loads W_1 and W_2 as well as the phase angles ϕ_1 and ϕ_2 at both substations are given. The feeders to substation No. 2 are overloaded, and it is desired to add a tie line marked Z_c . The problem is to find the new electrical conditions when the tie-line Z_c is of a given size in operation, or to find the size that would bring about the desired relief. Of particular interest are the currents in Z_b and Z_c . Readers are invited to contribute solutions to this problem.—Editorial Suggestion.

*The names of individuals given after each institution reporting investigations are those of persons with whom others interested should communicate. All institutions reporting research work should give such names.

NEWS OF THE INDUSTRY

Chronicle of Important Events and General Activities in the Technical, Commercial and Manufacturing Fields

SIR ADAM BECK ON THE PENDING WATER-POWER BILL

Chairman of Hydroelectric Power Commission of
Ontario Before Special Joint Committee
of House of Representatives

The special joint water-power committee of the House of Representatives held another hearing on the so-called "administration" bill on April 15, with Sir Adam Beck, chairman of the Hydroelectric Power Commission of Ontario, as the speaker.

Sir Adam Beck delivered an exhaustive analysis from his own point of view of conditions relating to water-power development in the Dominion and the sale of hydroelectric energy in Ontario as compared with what he knows of conditions in the United States, dealing in detail with the situation at Niagara Falls. He delivered a strong plea for monopoly in public utilities.

He presented a number of figures tending to show that under government control in Toronto the rate for electricity is about half the rate at Buffalo, and made other comparisons between rates in the United States and in Ontario. He said he had only a faint idea of the legislation proposed in the so-called administration water-power bill now in the House of Representatives.

The hearings before the joint committee will not be closed until the committee has heard Secretary Baker of the War Department, Secretary Houston of the Department of Agriculture and any members of Congress who desire to be heard. The framing of the final bill will therefore be delayed in the committee.

ONTARIO'S WATER POWER DEVELOPMENT

Sir Adam Beck said that Great Britain is dealing with water-power development very comprehensively at this time because of coal conservation, but that Ontario is surpassing the mother country in that respect. He has been identified with water-power matters in Ontario since 1903 or 1905. He traced the growth of legislation in Canada, saying franchises were originally granted to generate power at Niagara Falls on the Canadian side as follows: To the Canadian-Niagara Power Company, 100,000 hp.; to the Electrical Development Company, 125,000 hp., and to the Ontario Power Company, 180,000 hp.

The object of the boards of trade, merchants' associations, etc., in Ontario, he said, was to make this power available generally to the people of the district, and because of the great advance in the art of transmitting energy at high voltage economically to great distances, a desire was created in manufacturing districts to have this power available for them. Sir Adam pointed out that Ontario has no coal fields known at this time and that among the power difficulties there are the necessity for long transportation and the duty on coal. These difficulties have long continued.

In 1902, he said, various civic bodies appointed a committee to confer with the Legislature on steps to enable municipalities to undertake the generation of electricity. Two years previously the Legislature had refused the city of Toronto a franchise to develop power and instead had granted such a franchise to the Electrical Development Company, which had affiliated with it the Toronto Electric Light Company and the Toronto Street Railway Company. Finally the Legislature passed an act allowing the municipalities to borrow money on their own account for power and light development, and a commission was appointed to investigate. This commission, after eighteen months' work, practically said that power could be delivered at cost; but the practical difficulty of raising money was encountered, and further rights for development were granted to the Electrical Development Company.

Sir Adam then told of changes in the government following elections and of the passage of the present acts and amendments. He said:

DRASTIC POWERS OF THE COMMISSION

"We have power to acquire, by purchase or otherwise, on any terms and hold shares in any incorporated company carrying on the business of developing, supplying and transmitting electrical energy. We have power to appropriate the lands, waters, water privileges or water powers or works, machinery and plants or portions thereof of any person owning or operating under lease or otherwise or operating or using water-power privileges or transmitting electrical power or energy in Ontario which in the opinion of the commission should be purchased, acquired, leased, taken, expropriated and developed or used by the commission for the purposes of the act. Now, that is pretty drastic, but it is all subject to arbitration."

At the present time, the chairman of the Ontario commission said, that body has contracts with 225 municipalities. They pay all interest charges at 4 per cent and a sinking fund of 1.8 per cent, which retires in thirty years. They pay all charges of depreciation, operation, administration, etc. The chairman continued:

"We operate at the present time twelve systems. They will become interconnected eventually and form one great system. In this way we are attaining the object of the whole scheme, namely, that there should be one control only."

Sir Adam declared: "We want to create a real monopoly because we believe all these service undertakings should be a monopoly. There is little satisfaction in having competition in a telephone system, or a telegraph system, or even a railway system, and certainly not in an electric system in any community."

"The obnoxious poles and wires, the great dual cost of everything and the great dual investment that results because of the diversity created by these vari-

ous corporations covering the same field is undesirable from every standpoint."

As to the Niagara situation, Sir Adam said the principle laid down by the International Waterways Commission is that there should be an equal division of water for power purposes on all international streams, and pointed out that there is now pending an application that the United States government shall confer with the Dominion authorities regarding a proposal to allot another 10,000 second-feet to each government. This, he pointed out, is advanced as a war measure and will be justified even though the most efficient use is not made of the water.

Sir Adam said he believes that if this measure is carried through it would not be canceled after the war and would stimulate production after peace. He presented figures to show that the total power now being generated on both sides of Niagara is 653,000 hp. Of this amount, 265,000 hp., he said, is generated in the United States, which also receives 110,000 hp. exported from the Canadian side, making a total of 375,000 hp. available in the United States. This amounts to 40 per cent more for the United States than for Canada, he said, although the latter country generates 100,000 more horsepower than is generated in the United States.

The chairman of the commission went on to say that there is no intention on the part of the Canadian government or on the part of the commission to interfere with the present export arrangement, even though Canada is now short about 100,000 hp. of the amount that country needs. In order to permit a continuance of the export, Canada has arranged to do away with all sign lighting, window lighting and other uses of energy which in some quarters have been characterized as less essential. He said the power generated by the Province of Ontario has reduced coal consumption between 5,000,000 tons and 6,000,000 tons per annum. Motive power has been saved, use of cars has been saved, and duty on coal has been saved.

The estimated potential horsepower of hydroelectric energy in Canada, Sir Adam says, is about 50,000,000, and in Ontario alone about 5,000,000 or 6,000,000, with but 700,000 developed. At the beginning of the commission's work in 1910, he said, only 750 hp. was being delivered to the twelve municipalities interested. The commission has acquired up to date about eighty-six corporations through friendly negotiation and without resorting to the drastic powers given to it under the act.

Carry On—Buy Liberty Bonds

Irvington Varnish & Insulator Company Insures Irvington Citizens in War

The Irvington (N. J.) Varnish & Insulator Company, as a patriotic act, has paid for \$2,500 insurance under the government plan for each citizen of Irvington who has been called to the colors. The company volunteered to do this, not only for its employees who entered the service, but also for other citizens of the town. Under its offer insurance was taken for 460 people, including employees as well as other citizens of Irvington now with the military forces.

STUDY AND ANALYZE COST OF GIVING SERVICE

BY GERARD SWOPE,
Vice-President Western Electric Company

The electrical distributing business is becoming more and more one of service. The community expects good service and is willing to pay for it not only a price which will cover the cost of the service but one which will also provide a reasonable profit.

To-day, under the abnormal conditions that prevail, one of the dangers is that the business will not be studied and analyzed sufficiently. Increased expenses and extravagances will creep in, which will be difficult to reduce or eliminate when either normal or possibly for a time sub-normal conditions are at hand.

There is nothing more important for the industry than to have the individual members understand the elements that go to make up the cost of giving service to the community.

E. N. Hurley, when chairman of the Federal Trade Commission, emphasized this point and opened the eyes of manufacturers and business men in general to the great need of the recognition of its importance and the study and analysis of their own businesses.

The electrical manufacturers have worked up a comprehensive plan of cost accounting, and the electrical jobbers and the contractors are giving attention to this important phase of the work.

The electrical industry, as a whole, will be placed on a more permanently stable foundation if all the elements of the industry recognize the fundamentals involved in this question of scientific merchandising and cost of service.

DAYLIGHT SAVING

FOR PUBLIC SAFETY

Report of Committee of United States Chamber of Commerce Shows That Movement Had Support of State Committees

Daylight saving was one of the topics on the program of the United States Chamber of Commerce, which held its annual meeting in Chicago last week.

The report of the executive committee on daylight saving, of which A. Lincoln Filene, Boston, is chairman, showed that this movement had the direct support of a number of state committees on public safety and defense.

The committee was unanimous in its agreement that daylight saving ought to be a permanent measure to operate throughout the entire year, but it presented an alternate plan that if this suggestion were not feasible clocks should be advanced on April 1 and turned back on Nov. 30.

Since its last report the committee has received many communications from public utilities and others urging the all-year round plan as that which would bring about the greater saving.

The committee feels that the matter is well worth looking into further and suggested that it be empowered to go thoroughly into the question of extending the period of operation and take such steps as it may deem wise in carrying out its recommendations that daylight saving should be operated throughout the entire year. Already beneficial effects of daylight saving are felt and records of such savings are urged.

EXTENDING THE ELECTRIC OPERATION OF COAL MINES

Anthracite Operators Show that Great Saving of Fuel Will Follow Application of Electrical Energy in Mining

A bulletin issued by the operators of anthracite coal mines says, in forecasting larger use of electricity in their operations:

Millions of tons of coal now necessarily consumed in the mining operations would become available for general commercial uses should electricity be substituted for steam in operating the collieries of the United States. Earnest studies are now being made by experts in Washington and elsewhere to determine what can be done, and quickly, to expand electric power developments throughout the country, not only, nor even primarily, in connection with coal production, but also and mainly to meet the urgent requirements of war and other industries.

The anthracite industry is now consuming in its operations about 8,800,000 tons of the coal mined and prepared. Using steam there is no way to reduce this. It is estimated that with the entire industry turned over from steam to electricity for power, light and heat about 6,000,000 tons of such mine-consumed coal would be saved and be available to supply public demands.

Already substantial progress has been made in substituting electricity for steam in the anthracite operations. Latest complete figures show at the beginning of 1916 80,000 kw. of electric power used. This has been substantially increased since then, but there is yet a long way to go before electrical energy can be employed throughout and for all purposes.

Many anthracite companies have installed individual electric power plants to serve their own needs. It is an economic proposition, but the war demands upon electric manufacturing concerns have been so urgent that it is now virtually impossible to get additional machinery. Also it has been conclusively demonstrated, both in theory and in prac-

pendent business, and so is loath to install individual plants requiring large capital investment, which would be largely, if not entirely, lost when central power shall become available at lower cost.

Force to the Utmost—Buy Bonds

FLOOD CONDITIONS AT BINGHAMTON STATION

S. F. Bond Tells of the Precautions Taken to Protect Power House Under Severe Flood Pressure

Complying with a request of the ELECTRICAL WORLD, S. F. Bond, general superintendent Binghamton (N. Y.) Light, Heat & Power Company, has furnished information regarding the conditions at the new power house during the recent flood.

The ice field in the river extended about 12 miles (19.3 km.) below the plant and contributed largely to the unusually severe flood conditions.

The accompanying general view of the power house was taken when the water outside of the building went 6 ft. (1.8 m.) higher than the basement floor level. The crest of the flood reached a point 1 ft. 2 in. (35.5 cm.) higher than this. The bottom of the basement windows is 7 ft. 8 in. (2.23 m.) above the basement floor, and as an additional protection flood shutters of 2-in. (5.08-cm.) plank were installed in all these windows.

The other illustration is a closer view taken at the same time, showing more clearly the condition of the 33,000-volt outdoor switching and transformer station.

The power-house building is of reinforced concrete

OUTDOOR 33,000-VOLT TRANSFORMER AND SWITCHING PLANT WITH FLOOD 6 FT. HIGHER THAN BASEMENT FLOOR; CREST OF FLOOD 1 FT. 2 IN. HIGHER THAN THIS

tice, by such leaders in electrical development as Samuel Insull of Chicago and S. Z. Mitchell of New York that the central power plant makes the best and lowest cost system of supplying energy.

This is because the central plant, as the great heart of a big distribution system, which may reach out through a radius of 100 miles and more, can send the living energy of electricity to supply any and every purpose. In this way there results economy, as one use comes on when another drops off. For example, the great part of the anthracite mining load is off in the afternoon before lighting and electric railway service make their heavy demands for energy.

The anthracite industry is counting upon a big development of the central power plant as a separate and inde-

pendent business, and so is loath to install individual plants requiring large capital investment, which would be largely, if not entirely, lost when central power shall become available at lower cost.

construction up to the engine-room floor level, the walls and floor being reinforced to withstand an upward pressure due to a 10-ft. (3-m.) head of water. As practically all of the auxiliaries are placed on the basement floor, the operation of the station depends on keeping water out of the basement. There was no failure of floor or walls and only a moderate seepage at any time during the flood. A number of small leaks were checked by the use of sand bags, and when this had been done a 2-in. (5.08-cm.) ejector was sufficient to keep the basement dry. A 2-in. electric driven and a 4-in. (10.16-cm.) turbine-driven pump were, however, held in readiness for emergencies.

The great electrical industries are a vital part of the life of our nation. Their large manufacturing or producing plants, their multitudes of employees and dependents are a wholesome influence in our national life. In the crisis of war these establishments and their working forces are called upon to do without stint what they can do for the national aim of victory and righteousness. Not all are asked to risk life, but those who stay at home are privileged without exception to lend as they are able. So I say, buy the Liberty Bonds and speed the victory.

THEODORE N. VAIL,

President, American Telephone & Telegraph Company.

ENGINEERING PROGRESS IN ENGLAND IS MARKED

H. M. Hobart Recounts the Efforts Under Way to Eliminate Unnecessary Plant Expenditure and Conserve Coal Consumption

Observations upon engineering progress in Great Britain during the war were the theme of a recent informal address by H. M. Hobart of the General Electric Company at a luncheon of the Boston Section of the American Institute of Electrical Engineers, following the speaker's return from abroad. The progress of engineering in Britain has for long been extremely individual in character, he said. The electrical industry has been split up into many more divisions than in America, and the greater proportion of the small firms have aspired to manufacture many different kinds of things. A prospective customer received a large number of competitive tenders, and it was not unusual for the order to go to the firm which through faulty estimates had bid below cost. Prior to the war the electrical industry in Britain was at a low ebb. Many firms found their salvation in substituting munitions and other war work for electrical machinery. In so far, however, as they continued to manufacture electrical machinery this was done under improved conditions owing to the cutting off of German product and to the sudden demands of the Admiralty and the War Department for large quantities of electrical apparatus.

The general convulsion has brought about a serious spirit of investigation which is leading to a complete change of policy. Many new associations of manufacturers have sprung into existence, and even in cases where actual consolidations may not have been effected or in contemplation a policy of seeking to avoid destructive competition is much in evidence.

A government committee on coal conservation has been formed, and its interim report, issued in December, is of intense interest to electrical engineers. The report calls attention to the enormous waste in English electrical supply under present conditions. The public supply is obtained from about 600 undertakings, and in the London area there are over 100 generating plants selecting electricity besides nine traction stations, each supplying one of nine different railways. Two of these have each an installed capacity three times greater than would be ample for its present train service, and neither can increase this train service materially before the conclusion of the war. The plants are within a few miles of each other and in a district already provided with large, expensive, underloaded stations.

The report recommends the division of Britain into sixteen districts. Each district is to be supplied from

one or more generating stations. The loads on each station will be so great as to require the installation of generating sets of some 50,000 kw. each. These super-power plants will be placed at whatever locations represent the most efficient compromise as regards condensing water supply and coal supply. Electro-chemical industries and other suitable activities will be located near these stations and their load factor will be very high.

The carrying out of this project would, according to the estimates in the report, reduce from its present value of 80,000,000 tons down to 25,000,000 the annual coal consumption for power purposes (including railways) in the United Kingdom. This is on the assumption that the same amount of power will be developed under the new plan. But the power per employee is now only half of that in the United States, and must be at least doubled if Britain is to compete successfully in the world's markets.

The report has drawn forth an enormous volume of criticism. Much of this is based on the contention that the right conditions as regards cheap and plentiful coal and plentiful water are rarely found near one another in Great Britain. Others contend that the transmission and distribution costs associated with the electric scheme will be greater than the costs of conveying the coal by rail to stations located, as at present, near densely settled areas. Others display deep concern for vested interests and protest that in any case the change ought to be spread over a very long period.

"But the prevalent temper of the British is comparable to a sort of great awakening," said Mr. Hobart, "and I venture to predict that something of this sort, or at any rate something thoroughly equivalent in bigness and boldness, will be 'pulled off.'"

Probably a leading reason for the adoption of the national policy was that it would permit of an orderly continuance of shipbuilding and the employment of large numbers of men after the war and a freedom from the consequences of such industrial fluctuations in the demand for labor as might have occurred had private shipbuilding firms unduly extended their plants.

Closing, Mr. Hobart said that he was much impressed with the rapid progress lately made in England in the use of built-up iron-clad switch-gear as contrasted with the panel and cell systems used in America. Signs are appearing of its competition with American outfits for high-voltage work in generating stations. Although the British have finally and reluctantly taken down the sign, "Business as usual," which they took pride in displaying during the early stages of the war, an enormous amount of engineering progress is being made in Britain even in these darkest of dark days.

NEW YORK JOVIANS BUY

\$271,600 OF LIBERTY BONDS

Enthusiasm Marks Luncheon Meeting, Which Responds Liberally to Colonel Greenwood's Appeal
—McGraw-Hill Company's Contribution

Bonds and then more bonds were bought by the New York Jovians at the inspiring appeal and demand

The Third Liberty Loan

Campaign

Begins April 6

Buy YOUR Bond
of an
Electrical Man

BUY ELECTRICALLY, SAYS THE NEW YORK COMMITTEE

of Col. Moses Greenwood of the George H. Beach Service Company at a midday luncheon on April 17. Colonel Greenwood said that we are fighting the German people as well as the Kaiser. Every atrocious act of the German government has been approved by its people. We are fighting for something eternal, and civilization will be overthrown if we are defeated. He

placed every man in one of two classes and gave the reason why each should buy bonds. One class has relatives "over there" and should subscribe to its utmost to bring them safely home. The other class, which has no one at the front, must lend its money to keep the loved ones from going over.

The campaign for subscriptions was opened with an address by James H. McGraw, president of the McGraw-Hill Company, Inc., who pledged \$250,000 in behalf of the company. In an enthusiastic half-hour following \$21,600 was added to this amount by individual subscriptions.

Volunteers were called to pledge themselves to sell \$500 worth each of bonds during the remainder of the campaign. Nearly every one present stood up at this call, and it was estimated that if all "came through" a total of \$25,000 will be obtained.

All Over the Country Employees of Electrical Utilities Are Purchasing Liberty Bonds

STATION MEN OF THE COMMONWEALTH EDISON COMPANY, CHICAGO, IN LINE BUYING THE THIRD LIBERTY LOAN BONDS

The campaign for the third Liberty loan is now under way, and the opportunity is offered for the engineering profession in America to rise to the occasion with characteristic enterprise.

The success or failure of the engineer's part in this loan will depend not upon a few large subscriptions from some of the richer individuals in the engineering fraternity but upon the energetic co-operation of all the wiremen, draftsmen, linemen, rodmen, inspectors, superintendents, surveyors, foremen, laboratory men, students, calculators, testers and others who form the real backbone of the engineering forces of the United States; and it is to them that this appeal for subscriptions to the loan is addressed.

It is stated on good authority that there are 100,000 engineers in this country, broadly speaking. Surely every one of these men can afford the safe investment in a United States government bond of at least \$50, and probably much more. This would produce a substantial total.

Let every engineer take this loan to the limit of his ability as an investment for his own welfare and for his country and in that way become a partner in the greatest and most necessary engineering enterprise ever undertaken by the United States.

H. W. BUCK,
of Vile, Blackwell & Buck.

ZONE SYSTEM TO AID IN DISTRIBUTION OF COAL

Report of the National Committee on Gas and Electric Service Deals with the Plan
Effective on April 1

A report by the National Committee on Gas and Electric Service, of which J. W. Lieb is chairman, discusses in detail the zone system arranged by the United States Fuel Administration, in co-operation with the Director General of Railroads, to govern the distribution of bituminous coal during the coal year beginning on April 1, 1918.

The general effect of the zone system is to restrict Eastern coal to Eastern markets and fill the vacancy in the Central and Western States with nearby coal mined in those States.

In addition to the saving in transportation, the system will provide for the possible retention of something like 5,000,000 tons of coal for the Eastern States which heretofore has gone West, all rail. This tonnage can be readily utilized in the East. As an indication of the saving to be effected by the system, it will eliminate the movement of more than 2,000,000 tons of Pocahontas coal to Chicago and other Western points over a haul of about 660 miles. Chicago can obtain this tonnage of coal, and under this system must obtain most of it, from southern Illinois mines, with an average haul of 312 miles (502 km.). Allowing for the differences in quality in the two coals, there will thus be saved 11,400,000 car-miles or, very conservatively figured, 285,000 car-days. This will permit fourteen additional round trips of twenty days each from West Virginia mines to zone destinations, permitting an additional production of at least 700,000 tons of Pocahontas coal.

SAVINGS IN TRANSPORTATION

Similar comparisons show that on the movement of 550,000 tons annually from Kanawha districts to Wisconsin points there can be saved about 2,500,000 car-miles, with a consequent increased production of some 300,000 tons. On the movement from southeastern Kentucky to Chicago the saving will be about 800,000 car-miles and 50,000 tons in production. The elimination of the Indiana to Iowa movement will save 1,600,000 car-miles and add 100,000 tons in additional production. These are only a few of the instances of transportation saving to be effected by the system.

The movement of bituminous coal, which is regulated by the zone system, is about 300,000,000 tons, or 60 per cent of the total production. Based on this production, there will be saved on the round trip from and to the mines almost 160,000,000 car-miles. This will permit the same cars to make almost 300,000 additional trips from the mines, equivalent to an increase of 5 per cent in the production. The increase in total production in 1917 over 1916 resulting from all efforts was about 8 per cent.

A large part of the coal which the system will prevent from moving West out of the Eastern producing districts will be available for use in New England, in so far as it can be transported there. Production in the district supplying New England via all-rail routes can be increased somewhat, but there is difficulty in moving the amount of coal needed by all-rail routes,

and the capacity of the rail gateways to New England has been nearly reached. Improvements now being made will increase the capacity of the Poughkeepsie Bridge route, but it is impossible to escape the conclusion that provision must be made for a much larger movement by water in 1918 than in 1917, or New England and its people and industries will suffer. This situation will be made the subject of a separate study by a committee representing the United States Shipping Board, the United States Railroad Administration, the United States Fuel Administrator, coal operators in the territory involved, the railroads involved in the movement of this coal and consumers in the territory affected.

Under regulations of the Fuel Administrator, coal of particular quality or characteristics for special purposes, such as by-products, gas, blacksmith and metallurgical coal, will be permitted to move by permit beyond the limits imposed by the zone system.

The zone system affects all bituminous coal except:

1. Coal for railroad fuel, for which special arrangements will be made by the Fuel Administrator and the Director General of Railroads.
2. Coal for movement on inland waterways, which is in no way restricted by the system.
3. Coal delivered to Canada, which is subject to regulations of the Fuel Administrator.

Other matters covered are:

The National Committee on Gas and Electric Service has been requested by the Quartermaster's Department to furnish considerable information regarding power and other equipment for the different activities of this department now under way or contemplated throughout the United States and other countries. This is also true regarding the Ordnance Department.

The notice sent out some time ago regarding the possible cancellation of all coal contracts made previous to Aug. 23, 1917, has caused considerable anxiety among public utilities and others who have such contracts. This, in connection with the zone plan, has made the situation a very serious one, and the committee has been making every effort to secure definite action and decision.

The priorities committee of the War Industries Board is endeavoring to arrange to furnish sufficient steam and electrical machinery to the several nitrogen fixation plants and powder plants that the government is erecting. This committee has been called upon in an advisory way to furnish all information possible regarding the delivery to electric light and power plants of turbine units that are now under order at the manufacturer's as it will be absolutely necessary to requisition some of this apparatus for the government. The priorities committee is particularly anxious to interfere as little as possible with the operations of public utilities, and it is in extreme cases only that it will find it necessary to take over machinery ordered by the central stations.

The information that this committee was requested by Dr. Garfield, United States Fuel Administrator, to procure as to the addresses of isolated plants operating in the territory served by central stations is being tabulated as rapidly as received. There are still many localities to be heard from.

Many communications have been received from electric light companies asking if the Fuel Administration is considering rescinding the lightless nights order, now covering Sundays and Thursdays. This matter has been under consideration with a view to possible modification for the next four months. Such action is however, being opposed by a majority of the state and local fuel administrators.

The committee will within the next few days send out to all public utilities a letter calling attention to the additional money which is to be raised by the American Red Cross and asking that every assistance possible be given to this worthy cause.

MAKE OUR WATER POWERS AVAILABLE AT THE EARLIEST DAY

[This resolution was passed by the United States Chamber of Commerce at its meeting in Chicago last week.]

Whereas the Chamber of Commerce of the United States by an overwhelming vote in its referendum No. 24 indorsed recommendations which, in its opinion, would best bring about the utilization of the potential water powers of the country; and

Whereas the war needs of the government require a large increase in power for industries, for the conservation of fuel and for transportation;

Therefore, be it resolved, that the Chamber of Commerce of the United States hereby earnestly urges upon Congress the immediate passage of legislation which will make available at the earliest possible date the water powers of the country.

ELECTRICAL CONDITIONS IN EUROPEAN COUNTRIES

Stephen Q. Hayes Tells of His Observations in Great Britain, France and Italy—Electrical Distributing Centers

"Intense activity along electrical lines has followed the course of the war in England, France and Italy, and the need of the services of the electrical engineer behind the battle lines is constantly increasing," said Stephen Q. Hayes of the Westinghouse Electric & Manufacturing Company in a talk before the Boston Section of the A. I. E. E. on April 9. Mr. Hayes recently returned from a six months' trip in England and on the Continent, where he performed electrical work for the Allied governments. Mr. Hayes said that in England business conditions are in general better than before the war. Last year England did a larger export business than before the conflict began. All efforts are concentrated on speeding up production and cutting out non-essentials.

The control boards are doing most useful work handling the output of the factories and apportioning the production of war materials of different kinds. These boards, for instance, decide what percentage of materials shall go to English, French or Italian manufacturers.

Electrical factories in England are now working up to their limit. More than twice as many persons are in the employ of the English Westinghouse shops as before the war. About one-third of the output of these shops is munitions and the rest electrical machinery and equipment. From 20 to 25 per cent more electrical work is being turned out by the factory than before the war. The demand is tremendous throughout Europe for steam turbines and small motors, and prices are fabulous.

Great interest now exists in England regarding the proposed establishment of some sixteen electrical distributing centers with large modern generating plants and interconnected networks of transmission lines for the saving of fuel. Depending upon load conditions, it is expected that the line pressures required will range

from 6600 volts to 60,000 volts. There are about 600 separate municipal plants at present supplying the country which average only 5000 kva. in rating. It is estimated that 55,000,000 tons of coal could be saved yearly by interconnection and the use of units of 20,000-kw. to 50,000-kw. rating.

In the first three years of the war the electrical output in France has doubled. Hydroelectric energy is extensively used in connection with the operation of munition plants. The total estimated available water power of France is about 9,000,000 hp., and in 1916 about 1,500,000 hp. had been developed. Included in the latter were 750,000 hp. in the French Alps, 180,000 hp. in the Pyrenees district and 135,000 hp. in central France. Under construction in 1916 was 1,100,000 hp. in hydroelectric plants.

Mr. Hayes described the extensive railroad electrification work of Italy, and said that while figures of development are inadvisable for publication at this time, since the war began much has been accomplished in electrification. A point of interest is that when the British and French reinforcements were rushed to the Italian front after the collapse of the lines in the Trentino the electric locomotives on the Mont Cenis and other tunnel lines sustained from eight to ten times their normal traffic without failure. Portable power plants mounted on flat cars are used on lines near the front, the steam-generating and turbine-generator and switching equipment on separate cars. Some 100,000-volt portable substations on railway cars are in use in the war zone, and these require that the high-tension bushings of the transformers and oil switches be taken down for clearance reasons when moved. American electrical engineers are needed in the war zone.

RELIEVE THE UTILITIES FROM EXCESSIVE WAR BURDEN

[A resolution passed by the United States Chamber of Commerce at its meeting in Chicago last week.]

Whereas the maintenance of the country's public utilities in the highest possible state of efficiency is essential not only to the war program of the United States, but also to the nation's business, industrial and public interests; and

Whereas such efficiency depends upon the preservation of the credit of the companies providing public utility service; and

Whereas the increase of costs and the unusually onerous conditions of operation brought about by the war seriously threaten the ability of the public utilities to continue the furnishing of the necessary services they perform; and

Whereas the protection of the credit of public utilities is very largely in the hands of regulatory commissions and other public authorities, rather than in the utilities themselves;

Now therefore be it resolved, that the Chamber of Commerce of the United States recommends to state and local authorities that they recognize the unusual and onerous conditions with which public utilities are contending, and that in the interest of the nation, of business and of the public they give prompt and sympathetic hearing to the petitions of such utilities for assistance and relief.

Big Drop in Bituminous Coal Production

RATE OF BITUMINOUS COAL PRODUCTION IN LAST TWO YEARS

Dr. H. A. Garfield, Fuel Administrator, in a public statement declares that "unless there is immediate and material improvement in car supply efficiency the country faces the certainty of a serious shortage of bituminous coal."

Our "Will to Power"—Buy Bonds

RAISING RATES IN ORDER TO MEET HIGHER COSTS

Advance in Retail Power Rates by Minnesota Gas & Electric Company to Yield 20 Per Cent More Revenue

In making an increase in retail electric power rates the Minnesota Gas & Electric Company, Albert Lea, Minn., sent a circular letter to the customers affected and also advertised in the local newspapers, telling about the higher cost of fuel and other supplies.

H. T. Nichols, the manager, states in his letter that, after operation for months under most extreme conditions as to abnormal costs of fuel, material and labor, it is found absolutely necessary to obtain some degree of relief in the way of increased revenue to help offset very large operating expense increases. He gives the following increases:

Coal, 64 per cent; copper, 80 per cent; line hardware, 30 per cent; iron and steel wire, 35 per cent; meters, motors and transformers, 30 per cent; poles, 20 per cent; equipment and supplies, 35 per cent.

Mr. Nichols says in his letter, in part:

We had hoped that by increased efficiency and rigid economy and with an increase in the volume of business it would not be necessary to ask our customers for any assistance, and we have in this expectation carried the entire burden during the past year. Conditions have grown steadily worse, however, until we have arrived at a point where it is absolutely necessary to state the case frankly to our customers and ask them to pay an increased rate.

In the case of some customers a reduction will result in their cost per kilowatt-hour due to this rate revision, to others the increase will be almost negligible; but in the aggregate an increased revenue of something like 20 per cent should result for this part of the company's electric output.

As a matter of good business and of fairness both to yourself and the company the previous verbal agreements are to be replaced by written contracts.

It is sincerely hoped that present extreme generating costs will not long continue, and your company will receive the benefit of whatever proportionate reduction may be possible in the rate under this schedule immediately the company's fuel and material costs decrease.

For your reference we will state that the present average rate for all retail electric power customers in Albert Lea is approximately 3.3 cents per kilowatt-hour.

The new schedule will raise this average to nearly 4 cents per kilowatt-hour.

MEETING OF THE A. I. E. E.

IN CITY OF NEW YORK

Methods of Teaching Theory of Operation of Single-Phase Induction Motor Discussed—Liberty Loan Enthusiasm

To present to the engineering student "a physical conception of the operation of the single-phase induction motor" was the object of a paper presented by B. G. Lamme before the three hundred and thirty-ninth meeting of the American Institute of Electrical Engineers on April 12 in New York. Mr. Lamme said that most engineering students are able to visualize the operation of three-phase induction motors but are utterly lost in conceiving the operation of the single-phase type. The paper gives a method of explaining the single-phase motor in terms of the polyphase machine. The action of the motor is based upon the assumption of two equal and oppositely rotating primary magnetomotive forces combined with a synchronously rotating secondary magnetomotive force such as would be produced by direct-current excitation. Under load conditions a comparison is made between a two-motor unit, consisting of two similar polyphase motors coupled together and connected for opposite rotation, and the straight single-phase induction motor. Discrepancies between the resultant actions of two outfits were removed through extensive testing.

A. M. Dudley, in the absence of the author, abstracted R. E. Hellmund's paper on "No-Load Conditions of Single-Phase Induction Motors and Phase Converters." The paper is eighty-five pages in length and is written so that it can be read without following the mathematical data. A vertical line is printed next to calculations that may be omitted without harm to the coherence of the paper. Formulas for the determination of the fields, the stator and rotor magnetizing currents and the tertiary voltages for phase converters and single-phase induction motors are derived in the paper and methods for arriving at the results are given. "The case taken by the author is extreme," Mr. Dudley stated, "but there is considerable work to be done along these lines, and it is hoped that a start has been made by the presentation." The entire paper was based on calculated results, but it was shown by tests made after the work was completed that the calculated curves agreed very closely with actual oscillogram curves.

The two papers were discussed by B. A. Behrend, consulting engineer, Boston; Dr. M. I. Pupin, Columbia University; E. L. W. Alexanderson, General Electric Company; L. W. Chubb, Westinghouse Electric & Manufacturing Company; Prof. A. M. Gray, Cornell University; Selby Harr and C. A. M. Weber, Westinghouse Electric & Manufacturing Company.

W. A. Joubert, who spoke in behalf of the third Liberty loan, was applauded for several minutes, and B. A. Behrend, who was in the chair, told of the activities of the Institute in the loan. Return cards are to be mailed to every one of ten thousand members to ascertain the amount that the electrical engineering profession subscribes. Mr. Behrend expressed a hope that the subscription would be greater than that of any other organization in the United States.

Back Those Bayonets with Bonds

Associations and Societies

A complete Directory of Electrical Associations is printed in the first issue of each month on the next-to-last text page.

South Dakota Electric Power Association.—The annual convention of this association will be held at the Carpenter Hotel, in Sioux Falls, on May 15 and 16.

O. E. L. A. Annual Convention.—A convention of the Ohio Electric Light Association will be held at Cedar Point, Ohio, this year. Although the time is not definitely settled, July 10, 11 and 12 have been tentatively decided upon for the meeting.

A. I. E. E., Philadelphia Section.—“Electrification of Railroads in Its Relation to Communication Lines” was the subject of an address given by H. S. Warren before the Philadelphia Section of the American Institute of Electrical Engineers on April 8.

A. S. M. E., Cincinnati Section.—“The Economic Use of Coal by Communities” was the subject of an address before the joint meeting of the Cincinnati Section of the American Society of Mechanical Engineers and the Engineering Society of Cincinnati.

A. I. and S. E. E., Pittsburgh Section.—“The Electric Furnace for Annealing Treatment and Forging of Steel” is the title of a paper to be presented to-day by W. S. Scott before the Pittsburgh Section of the Association of Iron and Steel Electrical Engineers.

A. I. E. E., Baltimore Section.—On April 12 A. E. Bauhan, station superintendent Pennsylvania Water Power Company, delivered an address on “Power-Station Operation and Maintenance” before the Baltimore Section of the American Institute of Electrical Engineers.

San Francisco Electrical Development League.—At the regular weekly meeting of the league on April 10 Lieut. James S. Dagger, formerly of the Twenty-ninth Battalion, Canadian Expeditionary Forces, spoke on “The War on the Western Front” and “Labor and Its Relation to War.”

New York Electrical Society.—Major O. O. Ellis and Major E. B. Garey gave a joint address on “Using the Motion Picture to Train the Officers and Enlisted Men of the Army” before the New York Electrical Society meeting on April 18. Hudson Maxim spoke on “High Explosives in Modern Warfare.”

I. E. S., Philadelphia Section.—“Progress in Illuminating Engineering During the Past Year” was the topic of discussion by F. E. Cady of the National Electric Lamp Works, Cleveland, Ohio, and R. Pierce of the Welsbach company before the Philadelphia Section of the Illuminating Engineering Society on April 19.

Utah Society of Electrical Engineers and Dealers.—The spring convention of the Utah Society of Electrical Engineers and Dealers was held in Salt Lake on April 5 and 6. Among the important papers presented were: “The Goodwin Idea,” by C. B. Hawley, Inter-Mountain Electric Company; “Merchandising of Lamps,” by E. A. Evans, Westinghouse Lamp Company; “Trade Stimulation,” by W. R. Putnam, Utah Power & Light Company; “Credit Conditions,” by H. P. Stewart, Western Electric Company, and “The Trade Acceptance,” by A. D. McMullen, Capital Electric Company.

A. I. E. E. Section Meetings.—The following are some of the important papers presented before section meetings of the American Institute of Electrical Engineers: At Pittsfield, Mass., A. C. Crehore, “Modern Consumption of Matter and Energy,” April 11; Ann Arbor, Mich., Prof. J. C. Parker, “Hunting,” April 12; Boston, Stephen Hayes of the Westinghouse Electric & Manufacturing Company, “European Electrical Business in War Times”; Los Angeles, J. C. Ward, superintendent of generation of the Southern California Edison Company, “Fuel Oil Conservation,” April 9; Toronto, Paul Ackerman, “High-Tension Insulators from the Operating Viewpoint,” April 19. Officers nominated for the Toronto Section were A. H. Hull of the Hydroelectric Power Commission, chairman, and E. C. Pannell of the British Aluminum Company, secretary.

Recent Court Decisions

Findings of higher courts in legal cases involving electric light, power and other public utility companies.

Concurring Negligence.—Concurring negligence of a grading contractor did not absolve a city from its liability for personal injuries from electric shock caused by the city's negligence, according to the Supreme Court of Washington (170 P. 140).

Discrimination Owing to Free Service to City.—Discrimination by public service corporations is contrary to public interest, and where a requirement in a franchise that a telephone company shall furnish a municipality with free service necessitates overcharging other patrons the state, through the Public Service Commission, may modify or declare void such agreement, the Supreme Court of Indiana held (118 N. E. 531).

Contributory Negligence.—Where an employee of a cement company, while putting up steel handrails, was warned by the chief electrician of the cement company that if he touched certain power wires with the steel pieces it would kill him, as there were 22,000 volts on the line, in reversing a section of the handrail that it might be properly put in place touched the power line and

was killed, he was guilty of contributory negligence, relieving the power company from liability for his death, it was held by the Supreme Court of Alabama in *Dorough versus Alabama Power Company* (76 S. 963).

Jurisdiction of Commission.—A proceeding by a property owner to prevent an electric light company from disturbing the surface of a street for the construction and maintenance of a conduit for electric wires, on the ground that the permit for the work issued by the board of public improvements of a city was void because of nonconformity with the conditions of the ordinance upon which it purported to be founded, and, if valid, required a certificate of public utility from the public service commission, was not within the jurisdiction of the public service commission, the Supreme Court of Missouri held in *Missouri Valley Realty Company versus Cupples Station Light, Heat & Power Company* (199 S. W. 151).

Discontinuance of Service Though Amount Owed Is on Deposit.—The act of a lighting company in discontinuing service without notice upon user's default for past month's service was held proper where contract provided for discontinuance on default, and it was immaterial that the amount due was not in excess of the amount deposited by user to secure faithful performance of contract, the Court of Civil Appeals of Texas held (201 S. W. 205). That one became angry because of his light service being cut off for non-payment, the service being renewed immediately upon payment and request, does not entitle him to recover for mental suffering alone, there being no personal injury, damage to property or other loss sustained.

Franchise Validity.—Under Statutes 1901, p. 265, as to granting by municipality of privilege to locate poles or wires for light or power transmission, and Sections 3 and 5, as to publication of the application for the franchise and percentage to be paid to the municipality, an ordinance purporting to grant a franchise to construct and maintain poles and wires for the purpose of transmitting and selling electricity for “light and power” was void in so far as it attempted to confer the privilege of furnishing electricity for lighting purposes, and a charge could only be made for the latter or “power” franchise, in view of the Constitution, Articles 11, 19, granting to public service corporations engaged in the sale of electricity the right to enter the streets of a city and use them for laying down pipes, etc., for the purpose of supplying electricity to the inhabitants for “illuminating” purposes, the California District Court of Appeal held in *Town of Sunset versus Pacific Gas & Electric Company* (170 P. 1078). As plaintiff town had no power to charge a percentage on the gross annual receipts arising from the operation of an electric system for lighting, defendant, owner of the system, would not be estopped from denying that so much of an ordinance as attempted to impose such charge was unenforceable.

Current News and Notes

Timely items on electrical happenings throughout the world, together with brief notes of general interest.

Commonwealth Edison Men in Service.—On April 6, just one year after the United States entered the great war, 710 employees of the Commonwealth Edison Company had entered the military service of the United States. Men from the company are now in every branch of the military service. The company has published a complete list of the names of these men, together with their organizations.

Helping in the War by Watching the Mail.—A bulletin issued by the General War Service Committee of the Electrical Manufacturing Industry, addressed "To every electrical manufacturer," calls attention to the importance of avoiding unnecessary demands upon the government mail service. The Post Office Department has urged the committee to impress upon its associates the great advantage to both the department and the public of depositing mail matter earlier in the day and more frequently, and of having letter and circular mail, catalogs, etc., properly faced for cancellation and the short and long letters separated.

Report on General Policies of the War Trade Board.—The general policies followed by the War Trade Board and an outline of the board's labors for 1917 in the control of export and import trade are indicated in the first annual report to the President, which the board now makes public. The board has regarded trade agreements as being particularly important in the case of those European neutrals which are in trade relations with the enemy. Against these European neutrals, the report goes on to say, "temporary embargoes have been enforced pending the securing of information indispensable to permit the board to issue licenses." "The elimination of enemy advantage from our trade," says the report, "and to a considerable extent from that of the world, the securing and conserving of commodities essential to ourselves and those associated with us in the war, the bringing of shipping generally into the services most useful to us—these results cannot be accurately stated or appraised at the present time, nor have they been accomplished by any single act or agreement." The Bureau of Exports has handled approximately 425,000 applications for licenses to export and was at the date of the report passing upon between 4000 and 5000 applications per day. The Bureau of Imports, of more recent formation, had received to Jan. 1 5279 applications for licenses to import, upon which 4719 licenses, covering commodities of an aggregate value of \$237,810,949, had actually been issued. The personnel of

the War Trade Board numbered 1526, the report shows. The total financial obligation incurred up to Dec. 31 is \$541,498.80.

Pacific Gas & Electric Directors Re-elected.—At the annual meeting of stockholders of the Pacific Gas & Electric Company on April 9 all directors were re-elected and resolutions were passed ratifying all their official acts in 1917. A detailed report on operating conditions was presented by John A. Britton, vice-president and general manager. Mr. Britton also satisfactorily answered the questions propounded in an open letter to stockholders criticising the management which was recently circulated by a former auditor of the company. The re-elected directors are: Frank B. Anderson, Henry E. Bothin, John A. Britton, William H. Crocker, Frank G. Drum, John S. Drum, F. T. Elsey, D. H. Foote, A. F. Hockenbeamer, Norman B. Livermore, John D. McKee, John A. McCandless, C. O. G. Miller, W. G. Henshaw and George K. Weeks.

Enlistment of Students of Electrical Engineering.—The Provost Marshal General has sent the following telegram to the governors of all states: "Notify all local boards of the following amendment to Section 151, Selective Service Regulations. An additional sub-paragraph is added to paragraph 'e' as follows: 'Under such regulations as the chief signal officer may prescribe, a proportion of the students in institutions in which the Signal Corps has established a course in electrical communication who have completed at least two and one-half years of the course in electrical engineering, or its equivalent, in one of the approved technical engineering schools listed in the War Department may enlist in the Signal Enlisted Reserve Corps, and thereafter, upon presentation by the registrant to his local board of a certificate of such enlistment, such certificate shall be filed with the questionnaire and the registrant shall be placed in Class 5.'"

Research Information Committee Formed.—The following statement is authorized by the Council of National Defense: By joint action the Secretaries of War and Navy, with the approval of the Council of National Defense, have authorized and approved the organization, through the National Research Council, of a research information committee in Washington, with branch committees in Paris and London, which are intended to work in close co-operation with the officers of the military and naval intelligence, and whose function shall be the securing, classifying and disseminating of scientific, technical and industrial research information, especially relating to war problems, and the interchange of such information between the allies in Europe and the United States. The Washington committee consists of (a) a civilian member, representing the National Research Council, Dr. S. W. Stratton, chairman; (b) the chief of the Military Intelligence Section; (c) the Director of Naval Intelligence.

Commission Rulings

Important decisions of various state bodies involving or affecting electric light and power utilities.

Purchase of Lighting Companies by Public Utility.—The Indiana Public Service Commission has authorized the Indiana General Service Company, controlled by the American Gas & Electric Company, to buy the Marion Light & Heating Company, Marion, Ind., and the Muncie Electric Light Company, Muncie. The purchase price consists of the exchange of securities and the refunding of bonds heretofore issued by the companies purchased. Included in the price is \$1,000,000 capital stock of the Indiana General Service Company for each of the purchased companies and the refunding of bonds of each company at par and an issuance of bonds to cover floating indebtedness of the companies. The commission announced that the transfer represents no increase in total capitalization of the companies concerned. The commission staff made a valuation of the properties to be merged, and the commissioners said that the appraisal showed that the bonded indebtedness of all companies under the merger, plus the floating indebtedness, is not increased and that this total represents only about 50 per cent of the total physical valuation of the properties concerned.

Commission Power in Ohio.—The Ohio Supreme Court is expected to hand down in a short time a ruling on the power of the Public Utilities Commission to hear appeals on utility rates from cities which operate under special charters, or so-called "home rule" cities. Should the decision of the Supreme Court be in favor of the cities, the usefulness of the commission will be impaired greatly. The case originated in the natural-gas controversy at Cincinnati. The City Council first set the rate at 35 cents. The ordinance was submitted to vote of the electors and was defeated. The Council fixed a rate of 30 cents, and the Union Gas & Electric Company appealed to the commission. This was followed by an attack on the commission's jurisdiction and the objection was overruled. The case was then taken to the Supreme Court. Oral arguments were submitted on March 6. C. A. Radcliffe, attorney for the commission, asserted that if the court holds that the commission is without jurisdiction, its usefulness will be practically ended, as there will be nothing for it to do. Lawrence Maxwell, attorney for the company, derided the plea of home rule and said that if there is not state control there will be federal control. If cities adopt confiscatory rules, he said, companies will appeal to federal tribunals and invoke the United States Constitution in the effort to maintain their rights.

J. D. Ross has been reappointed as superintendent of lighting in Seattle by the City Council.

Walter D. Sultan, electrical engineer with the Pacific Gas & Electric Company for many years, has been commissioned a lieutenant in the Aviation Corps..

John B. Miller, president of the Southern California Edison Company, has, as a result of the change in titles, become chairman of the board of directors. This involves no change in his connection with the company, however.

W. Nelson Smith, who was for some years electric traction engineer with Westinghouse, Church, Kerr & Company, and recently efficiency engineer of the American Agricultural Chemical Company, is connected for the time being with Sydney E. Junkins & Company, engineers and constructors of Vancouver, B. C., as electrical engineer.

Clarence Floyd Hirshfeld, head of the research department of the Detroit Edison Company, has been commissioned a major in the Ordnance Department, Washington, D. C. He went to Detroit early in 1915 from Cornell University, where he was a member of the engineering faculty, to devote a considerable portion of his time to studying problems of electric industrial heating.

Henry D. Jackson, formerly of Timothy W. Sprague & Henry D. Jackson, consulting engineers, has joined the organization of Monks & Johnson, engineers and architects, Boston, as power engineer, taking charge of their power plant and heating work. Mr. Jackson's experience includes two years in the instrument and meter departments of the General Electric Company, four years with the Boston Elevated Railway Company, a short time with the Old Colony Street Railway Company of Massachusetts, investigation of the condition of a number of lighting plants and supervision of the changes made and consulting engineering work on power-plant construction, operation and maintenance.

Philip E. Edelman of St. Paul, Minn., has been awarded the Research Corporation fellowship in applied science on competition by a jury consisting of the president of the National Academy of Sciences, the secretary of the Smithsonian Institution, the president of the American Chemical Society, the president of the Research Corporation, and the chairman of the Engineering Foundation, upon evidence of scientific attainments, inventions and special fitness for advanced work. Mr. Edelman is an electrical engineering graduate of the University of Minnesota and has served as electrical engineer for important radio-communication interests. He is the author of "Experimental Wireless Stations" and other popular technical books, and has since February, 1917, devoted his time principally to research development work directed to increase the efficiency of the military power of the United States. He is at present working principally on important radio problems by special arrangement with the government.

Men of the Industry

Changes in Personnel
and Position—
Biographical Notes

F. W. Prince, for eighteen years employed by the Hartford (Conn.) Electric Light Company, has resigned as lighting superintendent to become quality expert for the Franklin Manufacturing Company. Mr. Prince was graduated from Trinity College in 1900, going with the Hartford company immediately on graduation as a lamp tester. In 1907 he became superintendent of the meter department and five years later lighting superintendent.

Townsend H. Soren, who, as reported in these columns on March 9, has been elected a vice-president of the Hartford (Conn.) Electric Light Company in charge of construction, was born in

T. H. SOREN

Boston and educated at the Boston Latin School and Harvard. He graduated with the degree of A.B. in 1893. Immediately after graduation he was employed by the General Electric Company at Schenectady and remained with that company until July, 1916, when he left to become assistant to the vice-president of the Hartford Electric Light Company. Mr. Soren's duties with the General Electric Company for a period of eighteen years were largely confined to the general supervision of the work of that company in connection with large electric railway developments in New York City. This work started with the equipment of the Ninety-sixth Street power station and substations of the Metropolitan Street Railways in 1897 and was followed by the equipment of the Manhattan Elevated Railway, the Interborough Rapid Transit Company and the Hudson & Manhattan Railway Company and the electrification of the main line of the New York Central & Hudson River Railway Company, including the construction and electric equipment of the locomotives.

J. H. Galt has been appointed assistant engineer of distribution for the Public Service Electric Company of New Jersey. He will have charge of the southern division at Camden.

Frank W. Frueauff, vice-president of Henry L. Doherty & Company, celebrated his forty-fourth birthday on March 29 at Delmonico's, New York, as the guest of 125 friends, the majority being business associates.

J. C. Rockwell has been promoted from manager of the light and power department to general manager of the Manila (P. I.) Electric Railroad & Light Company. Mr. Rockwell was graduated in 1914 from Cornell University with the degree of mechanical engineer. Following his graduation he engaged in track construction work. In 1906 he became superintendent of transportation of the Syracuse (N. Y.), Lake Shore & Northern Railroad Company. He was appointed general superintendent in 1909 of the Charleston (W. Va.) Interurban Railroad Company, and the following year was elected general manager of this company. In 1911 he joined the operating organization of the J. G. White Management Corporation, New York City, and was assigned to the Manila Electric Railroad & Light Company as manager of the light and power department.

N. J. Neall, consulting engineer, Boston, has received an appointment as major in the Quartermaster's Corps and is closing his office for the duration of the war. Major Neall was born in Philadelphia in 1875 and was graduated from the Massachusetts Institute of Technology in electrical engineering in 1900. Thereupon he entered the employ of the Westinghouse Electric & Manufacturing Company, later becoming engineer of protective apparatus for high-voltage transmission lines for the company. In 1906 he resigned from the Westinghouse company to take up consulting engineering work at Boston. Mr. Neall has been considered one of the best authorities on lightning protective equipment, and while with the Westinghouse company was associated to a considerable extent with Alexander J. Wurts, who was an authority on and inventor of lightning protective devices.

Obituary

Harry Herbert Trowbridge, general counsel for the Southern California Edison Company and head of its legal department since 1905, died suddenly at his residence in Pasadena on March 21. Before going to Los Angeles Mr. Trowbridge was connected with the legal department of the New York Central & Hudson River Railroad. The successful career upon which he had entered in New York City had to be abandoned on account of ill health, but even greater distinction awaited him upon the Pacific Coast, where as the legal representative of the Southern California Edison Company he soon became widely known as an authority upon corporation and public utility law.

TRADE & MARKET CONDITIONS

News of the Trade for the Manufacturer, Wholesaler and Jobber
of Electrical Equipment and Supplies—
Notes on Industrial Activities and Business Methods

JANUARY EXPORTS LOWER THAN THOSE OF DECEMBER

Drop Noticed in Volume of Trade in Wire and Cable,
Batteries and Motors—Total Exports for
January Reach the Sum of \$4,656,611

Electrical exports during the month of January, 1918, showed a considerable falling off from the month of December, besides being less than during the month of January, 1917. The total amount exported was \$4,656,611. There was a considerable drop in the exports of wire and cable as well as a considerable decrease in the export of batteries and of motors.

Figures for the seven months ended with January show a total of \$31,536,493, in comparison with \$28,217,968 for the corresponding period for the year previous. The figures in the following table were compiled by the Bureau of Foreign and Domestic Commerce:

	January		Seven Months Ended	
	1917	1918	1917	1918
Batteries	\$379,781	\$295,520	\$1,542,053	\$2,072,340
Carbons		93,543		*830,260
Dynamos or generators	271,742	252,429	1,466,111	1,249,074
Fans	43,660	68,541	188,521	353,481
Heating and cooking apparatus		59,652		*316,185
Insulated wire and cable	808,579	548,931	4,030,688	3,766,907
Interior wiring supplies, including fixtures	133,140	104,710	623,672	877,386
Arc lamps	973	671	6,951	1,315
Carbon-filament lamps	15,470	9,567	83,702	107,486
Metal-filament lamps	181,785	200,420	894,699	1,654,007
Magnetos, spark plugs, etc.		380,098		*2,137,946
Meters and measuring instruments	94,575	124,192	576,034	779,780
Motors	659,620	555,842	3,267,139	3,758,563
Rheostats and controllers		13,007		*106,619
Switches and accessories		271,196		*1,296,199
Telegraph apparatus, including wireless	24,808	9,208	173,388	174,102
Telephones	132,807	249,992	997,312	1,373,230
Transformers	133,539	174,001	656,341	1,179,228
All other	2,032,445	1,245,091	13,711,357	9,496,385
Total	\$4,912,924	\$4,656,611	\$28,217,968	\$31,536,493

*Included in "all other" prior to July 1, 1916.

of Boston, a grocery house of national reputation which has always taken unusual pride in its horse-drawn trucks. A national advertising campaign bearing upon the electric truck is about to be inaugurated, according to well-informed sources. The Boston fire department is seriously considering the purchase of an electrically driven ladder truck and possibly other equipment, based on the success of the Couple-Gear installations at Springfield, Mass., and elsewhere. Many of the trucks lately sold are turned over on the battery service basis, the Boston Edison company carrying the battery investment and meeting charging requirements according to an established rate schedule.

Will You Lend for Human Freedom?

LOOKING FORWARD TO WORLD TRADE AFTER WAR

Banks in Monthly Letters Point Out the Steps That
Are Now Being Taken by Europe, Urging
Action Here

That there will be a tremendous export market after the declaration of peace is taken for granted. To what extent the United States will be represented in that market is doubtful. England and France are openly making preparations to enter it in a big way, and it is generally believed that Germany is not without some well-laid plans. In the United States little of note has been done. The Webb bill is still hanging fire, needing some real interest and enthusiasm to push it through.

This state of affairs is recognized by the banks, which are urging the manufacturers of this country to face the situation and take some action. The following excerpts are from the regular monthly letters of two of the more prominent New York City banks.

The American Exchange National Bank in urging that American manufacturers and exporters organize to take advantage of the Webb bill for pushing foreign trade in competition with other countries says:

"Germany is strengthening her cartel system, and England and France are organizing syndicates for this purpose. It will not do to wait until peace is restored. Hereafter competition in international markets will be national rather than individual, and the race is likely to be won by the nation that is best prepared before the declaration of peace."

The Guaranty Trust Company describes in its monthly letter the strenuous efforts being made by Great Britain to restore her commercial and financial position after the war. No secret is made of the fact that she expects a period of intense competition for the markets and the carrying trade of the world, the letter states, nor of her intention to be as fully prepared for it as possible. It goes on:

"In preparation for this intensive development of her resources, Great Britain is taking what is probably the most remarkable inventory ever attempted. Under the general direction of the Ministry of Reconstruction, the Ministry of Munitions, Department of the Foreign Office and Board of Trade, and other governmental agencies, nearly a hundred committees are busy collecting information regarding agricultural, mining, industrial and commercial conditions within the empire. The inquiries of these committees touch the life of the British people in all its phases."

The British banks are preparing for the demands which will be made upon them for capital to finance the program of restoration and new developments. By amalgamations, the letter says, they are concentrating great reserves of capital for a vast credit structure.

Our Boys Go—Shall Money Fail?

ELECTRIC TRUCKS ARE IN HEAVY DEMAND AT BOSTON

Increased Cost of Skilled Labor and of Horse Feed
Are Important Factors—Deliveries in
Good Condition

Despite the fact that very little publicity has been given to the campaign, electric road trucks have come to be in extraordinary demand of late in the Boston district. One of the best-known dealers has sold no fewer than sixty-eight trucks within the last three months, ranging in size from 6 tons to 1 ton. In some cases deliveries have been made within two weeks of receipt of order. The increased cost of skilled labor and of horse feed are important factors in the advance of the electric truck in this territory. Recent purchasers include forwarders, grocers, iron and steel dealers, confectioners, coal merchants, milk dealers and newspaper-stock handlers. A 5-ton General Vehicle machine has just been purchased by the S. S. Pierce Company

VARIOUS OUTLOOK UPON ELECTRICAL GLASSWARE

Scarcity of Labor and Fuel Supply—New Discounts and Packing Charges Formulated by Producers

Scarcity of labor and curtailment in the supply of fuel are having a restrictive effect on the output of glassware of every description. Opinions differ as to just how far current conditions may affect the stock and supply of electrical glassware for this or succeeding seasons. Wages of skilled labor in the hand and machine glass works have been advanced 25 to 30 per cent, this having become effective when the new "fire" was started early in December. Production during the temporary federal fuel schedule down to 75 per cent of capacity. It is also reported there are some sizes and sizes of glass that are already out of the market. The statement that no new electrical glassware will be obtainable in this market before April is flatly denied.

Prices are also said to be subject to a sharp rise. Inquiry at sales agencies in the East of the principal glass works of the Pittsburgh and other districts confirmed this opinion to some measure. Either higher lists or shortened discounts may be expected to prevail.

Prices quoted are f.o.b. factory, and there is no insurance of delivery or against breakage. There was a time when breakage was insured with the packing charge, but this practice has been abolished. On Feb. 1 the packing charge was increased by producers from 25 to 33 1/3 per cent. Deliveries are now six months in arrears, with the embargoes rendering shipments decidedly uncertain.

The advance spring business is stated as exceeding expectations, especially in fixture lines; in fact, representing an improvement over last year. Export trade is reported as enormous. On the other hand, plants have been running a part time only. It has been difficult to obtain as strong a skilled force of workmen as was desired, while the question of fuel has been a problem and raw material is none too ample.

METAL MARKET SITUATION

Wire Prices Will Probably Remain Unchanged—Tin Quotations Running Wild

If manufacturers of wire products for electrical uses are figuring on a higher figure for copper, and therefore an advance in the selling cost of their goods, it looks as if they are to be disappointed, with the possible exception of weatherproof. An authority of accepted standing in the metal world says that the large profits realized by the copper industry in 1917 go a long way toward offsetting the claims and arguments that are being advanced for a higher price on copper. The truth is that there is hardly a producer of standing who will go on record as saying that anything more than 23.50 cents for the metal is necessary for the welfare of the industry or the country. There is said to be no price for Straits tin, and quotations for the other kind are in consequence running wild.

NEW YORK METAL MARKET PRICES

THE WEEK IN TRADE

HOW much the electrical trade is hampered by the slow and indefinite delivery of merchandise is not easily determined. From general reports, however, the embargoes on certain material produce trying conditions at times. Possibly this trouble may be relieved, to some extent at least, by the recent order of the Priorities Board placing on preference list No. 1 "plants manufacturing electrical equipment." The delays in shipments on electrical goods other than specified for government requisitions are occasioning shortages bordering on the acute.

Nearly every section reports that conduit is selling in excess of the supply, which also seems true of lamps (with the demand increasing in the far West), rubber-covered wire and large motors. There is also a satisfactory demand for motor sewing machines and other household devices. Jobbers are also stocking up heavily on fans, anticipating a summer of protracted heat to follow the long and cold winter.

Collections are universally conceded to be up to the mark, with credits closely looked after.

NEW YORK

Sales in regular lines for commercial uses have been halted to an appreciable extent by unusual weather conditions. The storms which have prevailed, of extreme severity for this time of year and extending over the entire eastern section of the country, have, jobbers generally say, had a deterrent effect on business. Government orders for equipment are still a ruling factor. Prices have not been affected, but stocks are far from ample.

Freight congestion has not been greatly relieved, and deliveries are the main topic of discussion. Shipments of iron and steel products are far behind. Labor shortage at the factories is also the cause of some anxiety.

Collections are reported as in fair condition, with some sections of the trade well pleased with the situation. No relaxation in the scrutiny of credits is noticed.

PAPER AND CLOTH INSULATION.—Very little change has occurred recently in paper insulation, and trade is steady. In respect to cloth, however, an entirely different state of affairs exists. With the rapid advances in cotton the price of cloth insulation has also been fluctuating rapidly. Within the last two weeks the cost was marked up from 20 to 25 per cent, and selling figures, according to influential authorities, are likely to change in forty-eight hours. Stocks are of fair size in the hands of leading producers, but with jobbers and dealers they are described as low.

COLLECTIONS AND CREDITS.—Throughout the metropolitan territory, where accounts and regular settlements receive the attention due their importance, collections are mentioned as good if not uniformly favorable. Credits are closely looked after, and the commercial rating of the buyer, especially on new accounts, is carefully weighed and considered.

LAMP FIXTURES.—Quite a volume of business is recorded for replacements and renewals of civilian equipment.

GLASS INSULATORS.—Buyers and distributors report no further price advances, and manufacturers, whose productive capacity is reduced 50 per cent by government order, seem to have enough stock to meet the demand. Of course transportation facilities are hampered by embargoes and other restrictions.

MOTORS AND GENERATORS.—On the larger sizes deliveries are yet far in arrears. Sales of the smaller-horsepower apparatus and machines, out of stock and second-

hand, represent a steady movement, the demand far exceeding the supply. Prices have not changed.

POLE AND LINE MATERIAL.—Spring work, caring for replacements, maintenance and general wear and tear of the long and trying winter in central stations, power houses and transmission lines, is well under way. Pole and line material and hardware are selling in volume up to expectations.

PORCELAIN.—No general advance has materialized, although one was anticipated by several jobbers who had been advised of a pending change by manufacturers. It seems that quite a large stock of knobs, clats and bushings is held at the plants awaiting shipment.

CONDUIT.—With the government in the market for rigid conduit, shipments out of Pittsburgh to Eastern points are small and uncertain. The lowering of prices noted before is also reflected in flexible-steel armored conductors.

CHICAGO

The volume of the jobbers' business continues about the same, with a spotty condition particularly prevalent during the last week. Prices remain firm with no change. There is much evidence, however, which points to an upward revision of steel prices at the next revision date. These indications are taken very seriously in the Chicago district. The movement of goods still continues along the same line, with industrials active and central stations quiet. The passing of the Finance Corporation bill is expected to help central stations largely engaged in war business, but a few large plants in this territory see no way in which it will be of direct benefit to them.

CONDUIT.—The condition of the conduit market remains unchanged, the demand exceeding the supply, especially for the larger sizes.

WIRE.—One manufacturer of weatherproof wire has just placed an order for cotton at 62.5 cents a pound. With cotton at such prices it is reasonable to expect changes in wire prices.

FANS.—Some Chicago jobbers are taking on extraordinarily large stocks of fans. It is believed that a hot summer such as usually follows a cold winter will produce a market for fans this year which will clean the shelves of the industry. It may be pointed out that fan manufacturers have been limited in their production this year on account of the lack of material for making fans. When jobbers placed their orders last winter they were told by the manufacturers to state at that time their entire year's requirements, as the manufacturers would guarantee absolutely no more. Jobbers are pointing these facts out to the dealers in a spirit of helpfulness, as it is considered to be a certainty that a hot summer will produce a fan shortage that will find unprepared the dealer who has not put in his stock in advance. The most popular types of fans, judging from the jobbers' stock, appear to be the 9-in. and the 10-in. The 9-in. fan is considered a happy medium between the 8-in. and the 12-in., especially in view of the high prices of the 12-in. fans.

ELECTRIC SEWING MACHINES.—There is considerable activity in the electric sewing-machine market. Established makes are moving with a continued rapidity, and some new makes are coming into the market.

ELECTRIC RANGES.—The change in the character of the central-station load curve caused by the daylight-saving movement makes the electric range, the manufacturers contend, a more desirable load builder than ever, since it will help fill in that new and deep valley created in the load curve between 5 and 8 o'clock in the evening.

AUTOMOBILE ACCESSORIES.—The trade in automobile accessories is starting off well this spring. A very good business is expected for the year owing to the fact that most people are paying more than usual attention to the repair of existing equipment.

CENTRAL-STATION BUYING.—While financing difficulties have slowed up central-station purchasing, there are one or two projects of fairly large character in the Middle West which, it appears, may find a solution of this problem.

BOSTON

Trade continues extremely active. Collections do not show much recession on account of the Liberty loan drive, although credits are being more carefully watched than for some time. It is still very difficult to find any jobber or dealer who will testify that the freight delivery situation on the railroads shows much improvement. A movement toward increasing the coastwise shipping facilities to and from New England is taking shape, and this should supplement the railroad service in time to a most helpful degree. With the exception of conduit and porcelain, jobbers are pretty well stocked up. Little change in price was noted during the week except an advance on Hunt industrial electric trucks to conform to an increase of about 10 per cent in alkaline storage-battery prices, April 10. The contract under which William F. Kearns & Company of Boston are to construct a twenty-million-dollar United States Army waterfront terminal at Boston during the next eight months was signed at Washington April 11. A large quantity of electrical equipment for lighting and power service will be required by this great installation.

LAMPS.—The supply is slowly increasing, but the manufacturers are far from having caught up with orders. Seasonal conditions are favorable to the overtaking of demand by production in due course.

INDUSTRIAL ELECTRIC TRUCKS.—Inquiries are well maintained, with government or closely allied business the basis of most orders. Shipments range in a general way from two weeks upward, depending upon the extent of departure required from standard equipment. A moderate price advance on Hunt trucks is reported, effective April 10.

VACUUM CLEANERS.—A flood of orders is pouring into the factories, and it is difficult to accumulate any considerable stock. One representative factory, visited within a few days, is working day and night and is far behind on orders. Business is being handled from the Orient, South America and the Antipodes, as well as in this country. Railroad and express shipments are slow, and many damage claims are being received. Women are being utilized in this class of production up to the point where highly technical assembly work begins. Men are required for the heavier setting-up work, and for duties of an engineering nature in vacuum-cleaner manufacture.

FANS.—The manufacturers have completed about all of this season's production, according to reliable advices. Large shipments are at present en route between the factory and the jobber, and the retailers are getting pretty well stocked up from the initial and succeeding distributions by the jobbers.

MOTORS.—A fair supply is now reported in standard equipment up to and including 20 hp. Prices are firm, with no change in sight. The demand for motors is apparently falling off slightly, but any permanent recession is hardly to be expected during the period of the war.

CONDUIT.—Nothing very optimistic can be said about the conduit situation at this time. Over and over one encounters the plaint of deferred deliveries on purchases made six to nine months back. Building operations are very flat. Fortunately temporary wiring is possible in many industrial installations handling war orders, and the needs of the international situation do not depend, so far as this class of work goes, upon putting all circuits in pipe. Ship construction is likely to demand more and more conduit within the coming summer, and the drain upon stocks is likely to be heavy even in some of the smaller sizes at present accumulated through the stagnation in house-wiring activity.

MOTOR CONTROLLERS.—Manufacturers are well ahead of the motor makers, speaking generally, on controller deliveries. Most orders can be traced to government requirements. Good shipments can be had from the factory on standard equipment, but delays are being experienced in transportation. Prices are steady, and a slight slowing down is noted in business.

INDUSTRIAL HEATING EQUIPMENT.—Despite the lateness of the season, a considerable demand is noted for heating units for out-of-the-way service.

ATLANTA

The market for large apparatus through the central stations has been comparatively dull of late, the tendency for the week being along the same line. Of course, there are exceptions, where a few companies are buying equipment for government or quasi-government account in connection with nitrate and shipbuilding work. Turbine shipment promises show no improvement. Several water-power developments have been held up temporarily owing to incomplete financial arrangements and uncertainties regarding public service commission decisions on rate increases. Although quite a number of operating companies have increased their rates so far, it is expected that the various state commissions in the Southeast will be literally deluged with applications in the near future, as it is imperative that some of these companies secure immediate relief.

The great demand for textile products from both government and commercial channels continues actively in mill construction. The Franklin Cotton Mills, Concord, N. C., have been capitalized for \$1,000,000. While general building work is away off in the Southeast, certain areas show a stimulated movement, as reflected in the spotty demand for staple electrical supplies. Speaking generally, shipments are coming in slightly better when compared with the last two weeks. Jobbers report that standard goods are moving more freely. The week has witnessed a good demand from outlying sections for circular loom, knobs, tubes and standard rubber-covered and weatherproof wire.

FIXTURES.—The volume of sales as recorded in the larger cities is substantial, but a sag is noticeable in the requirements from the less populous sections. Deliveries on the whole are poor.

PORTABLE LAMPS.—Business is excellent. A singular trend of the trade which it is interesting to note is the increasing demand for floor lamps, with a corresponding decrease in the call for table portables. Shades are active, the mixed colors appearing to be growing more popular for both floor lamps and living-room portables. The solid-colored shades for small and boudoir types of portables are moving briskly as well. Deliveries on shades are reasonable compared with those now being obtained on portables.

WASHING MACHINES.—It has taken a long campaign of education for this device to "break in," as it were, but the volume of business now being transacted justifies the efforts on the part of the manufacturers and jobbers. There is no doubt that activity will continue to increase, especially as the servant problem grows more difficult each day.

SEATTLE

Despite a general lay-off to participate in the drive for third Liberty loan honors, a gratifying and sustained volume of business is reported by both jobbers and retailers. Collections were excellent and demands for credit exceeded the past several weeks. From the electrical jobbers' standpoint the past week is unmarked by any unusual developments. Sales to shipyards and allied industrial plants were heavy. New building is maintaining the pace set early in the year. The government buying dropped off considerably, but heavy sales of the past few weeks will easily offset any decrease.

Lamp, rubber-covered wire, large-motor and conduit shortages still exist. This shortage particularly is causing concern, as the demand, contrary to expectations, is still on the increase. This shortage is especially acute on lamps of larger sizes. The wire situation is accentuated materially by a heavy demand for house and industrial wiring purposes. The arrival of several large shipments recently relieved the situation temporarily, but stocks are tightening again. While the shortage in motors exists, particularly in the larger sizes, the demand is considerably less in the last two weeks. Fresh demands from two Puget Sound shipbuilding cities are anticipated shortly. Eastern manufacturers report an available supply of conduit for coast distribution, but local shortages are increasing owing to the lack of closed freight cars. Prices remain steady, with no increase or decrease expected in the near future.

Labor shortage in the Sound cities has never been so

serious, according to authorities. This applies to practically every industry, and the electrical trade is not excepted. The employment of women in certain industries has afforded a measure of relief, but their capacity for work in war industrial establishments in this section is very limited. The Inland Empire Spokane district reports that unless conditions change before harvest the present labor supply will be sufficient for the increased work then. It is stated that there will be no need to bring soldiers from cantonments to help with the spring work. This step was considered.

New wooden shipbuilding companies of Seattle signed contracts for eight ships of 3500 tons capacity with French interests. Work will begin as soon as the project is sanctioned by the United States Shipping Board. An increase of 151 industrial plants under the factory inspection law in the State of Washington was last year shown by actual figures. The figures show 44,000 more men employed in industries and an increase of 2500 female employees.

Substantial progress is being made toward relief from the shortage of cars to move lumber and other products from Washington and Oregon.

SAN FRANCISCO

During the past week the momentum of electrical business, which had slowed down, again became accelerated, and several contractors whose lists of jobs on hand had dwindled to the finishing point suddenly found a long list ahead of them. The most noticeable feature of the past week's business has been the number of calls for household electrical appliances, particularly washing machines and vacuum cleaners. An increase in the range business was also reported, probably as a result of effective and patriotic advertising, for little regular effort has been made this year on account of power shortage.

Los Angeles reports that the Harbor Commission, in accordance with its determination that harbor industries are to be supplied with municipal power, has decided to refuse permits to electric lines crossing tidelands under its control, and this decision will affect a score of private power lines unless they retire from the field.

Industrial work reported during the week includes a 300,000-bag rice mill at Marysville, a new cannery at Biggs, an addition to the American Can Company's plant in San Francisco and electrical dredging and steam crane work along the Oakland estuary.

The southern California campaign having been definitely launched after the preliminary ground work, and investigation being under way in the rest of the State, a noticeable increase in the quality of electrical merchandising is evident. There is plenty of spending money on account of top wages by industrial plants and the good wages to be paid fruit and berry pickers because of scarcity of help. These facts are a stimulus to the country dealer, combined with the decreasing number of house-wiring jobs.

SEWING MACHINES.—A nation-wide advertising campaign, carried on by the largest manufacturer of portable electric sewing machines, has resulted in a tremendous business that is diverted through electrical dealers. Red Cross work and its demand for speed are chiefly responsible, but the low price of the portable electric machine has resulted in many sales. Similarly there has been a demand for sewing-machine motors only so great that local jobbers can secure only a portion of their quotas of orders at the factory. Several times there has been no Pacific Coast stock even on certain types of electric machines, this condition being attributed, first, to lack of sufficiently seasoned wood for the bases, and, second, to shortage of motors.

SWITCHES.—Knife-switch sales fall below those of last year, and a large portion of the present year's sales are attributed to the filling of back orders, based on previous demands.

ELECTRICAL FIXTURES.—Designers and manufacturers of house and hotel fixtures report that their business is poor. On the other hand, there never was such a large sale for industrial reflectors, and it is conservatively estimated that this business is running 25 per cent in advance of 1918. Stocks and deliveries are good.

Current Prices of Electrical Supplies

New York and Chicago Quotations

THE prices quoted are those prevailing in standard packages of specified lots on apparatus and appliances in Eastern and Middle West markets at the beginning of business on Monday of this week. They are in all cases the net prices or prices subject to discounts from standard lists of contractors, central stations, dealers and others engaged in the resale of such goods.

Prices in Southern and other nearby markets will rule about the same as those in the Middle West, although slight modifications to cover increased freight and local demands should be expected. In the Far West and on the Pacific Coast the prevailing prices are naturally higher, covering as they must increased

freight and the necessity of larger stocks with increased interest and warehouse charges on account of the distances from sources of supply, infrequent turnover of stock and uncertainty as to delivery of goods in transit. Moreover, the Far West presents a wide variation in demand due to a small population spread over a wide area in agricultural and mining communities, as contrasted with the denser population of the East and Middle West, their nearness to the sources of supply, the more frequent turnover in stocks and the constant demands which arise in industrial centers. Price variations may be due to difference in grade of products of different manufacturers, to local conditions, or to both.

NEW APPARATUS & APPLIANCES

A Record of Latest Developments and Improvements in Manufacturers' Products Used in the Electrical Field

Brass Canopy Fixture Switch

Pass & Seymour, Inc., of Solvay, N. Y., are marketing a compact brass canopy fixture switch. The porcelain base of this device is arranged to be used on both 3.25-in. (8.25-cm.) and 4-in. (10-cm.) outlet boxes, and is fitted with an insulating lip which prevents the grounding of the brass canopy. It therefore needs no insulating ring or insulating joint. This feature makes it especially desirable for metal ceilings or walls. It is possible to loop the line wires over the terminals of the switch and carry them directly to the terminals of the unit without splicing. The brass canopy snaps on or off instantly without the use of tools. It is fastened to the base by twin spring lugs, easily located by the unobtrusive buttons on opposite sides of the canopy. It can be equipped with a nipple, porcelain bushing or fixture loop for supporting the glassware.

Variable Self and Mutual Inductometer

The inductometer produced herewith consists of two pairs of stationary coils and one movable coil, the latter being mounted on a disk placed between two outer plates holding the stationary coils. The disk may be rotated and has two scales, one calibrated in millihenries reading self-inductance, and the second in degrees. The instrument is ordinarily provided with a maximum inductance of 50 millihenries, but instruments with higher maximum values or lower values can be obtained.

The inductometer has six link-shaped coils. The four fixed coils are mounted in pairs in the two outer fixed plates, which are held together by four screws and separating pieces to form the body of the instrument. The two movable

ROTATING DISK CALIBRATED IN DEGREES
AND MILLIHENRIES

coils are mounted on the inner disk and are placed with their long axes at right angles to a diameter. The outer plates and the disk are made of molded bakelite. To use the instrument as a variable mutual inductometer the fixed and movable coils are used as primary

and secondary respectively and no connection is made between them. The mutual inductance is found by subtracting a constant from the scale reading and dividing the remainder by two. This constant is given with each instrument, although it may be readily determined by the user at any time. It is claimed that errors due to stray field effects are eliminated and that the meter has a desirable ratio of maximum inductance to minimum inductance. It is made by the Leeds & Northrup Company, 4901 Stenton Avenue, Philadelphia.

Cut-Out Switch with Interchangeable Knock-Out

A service cut-out which consists of a knife-blade switch inclosed in metal box with interchangeable knock-outs for conduit connection is being manufactured by the Palmer Electric & Manufacturing Company of Boston. The fixed jaws of the switch are secured to the bottom of the box. The cut-out

NO CURRENT-CARRYING PARTS ARE
WITHIN REACH

block and the movable jaws of the switch are secured to a hinged cover pivoted at the middle point of the box and having a flange like a letter box. When the circuit is broken by opening the hinged cover, the cut-out and fuses are exposed without making any current-carrying parts accessible. The half-tone of the box in the open position shows that it is impossible to make a "fished" connection to the service contacts. When the switch and cut-out are mounted in connection with a meter adapter the service wires are protected by conduit and no current-carrying parts are accessible although the service switch and fuse are easily accessible.

Flange-Type Cable End-Bell

The Electrical Engineers' Equipment Company, 710 Madison Street, Chicago, has made improvements upon its cable end-bell, consisting principally of a flange which is cast about the neck of

the bell where the lead-covered cable enters. This flange is arranged so that adapters can be bolted to it for mounting the bell upon any size of conduit or for any size of clamp or wiped cable joint. In case the bell is to be mounted upon conduit, a brass bushing is provided, which is clamped in between the bell flange and the flange upon the pipe adapters. The brass bushing forms the ground connection. With this arrange-

BRASS BUSHING FOR CONDUIT MOUNTING
FORMS GROUND CONNECTION

ment the bell can be installed without being turned, which is an advantage, especially when the bells are to be installed in limited spaces where there is not sufficient room to revolve them. All cable end-bells being manufactured by the Electrical Engineers' Equipment Company have this feature.

Ornamental Gas-Filled Lamp

The accompanying illustration shows a unique ornamental gas-filled lamp manufactured by the Victoria Lamp

NEW GAS-FILLED LAMP COMBINES ORDINARY
LAMP BULB AND SHADE IN ONE

Works, 507 Union Place, Union Hill, N. J. It is claimed that this lamp produces an indirect non-glare light which will not injure the eyes. The lamp is interesting in that it combines an ordinary gas-filled bulb with an ornamental lamp shade. The lamp, known as the

"Liberty," is made of plain white glass with ornamental decorations in green, gold, blue and other shades that will harmonize with chandeliers or room decorations.

Motor Attachment Plug for Home Devices

The accompanying illustration shows an exploded view of a motor attachment plug now being placed upon the market by Harvey Hubbell, Inc., of Bridgeport, Conn. The part to which the contact blades are attached has

ATTACHMENT PLUG THAT FITS IN ENERGY-CONSUMING DEVICE

slots or grooves that fit into the energy-consuming device. All current-carrying parts of the detachable portion are carefully concealed within arcing chambers to prevent accidental contact therewith. The plug is constructed of heat-proof composition and measures 1.62 in. (4.1 cm.) in length and 1.3 in. (3.3 cm.) in diameter at the bottom of the base. The plug is especially designed for use with devices employing small motors such as vacuum cleaners and floor scrubbers.

Bus Support Equipped with Adjustable Base

Busbar supports which are designed to fit several sizes of insulated cable and which are also equipped with adjustable bases are being manufactured by the Lewis & Roth Company, 1012 Liberty Building, Philadelphia, Pa. The support, which is made of malleable iron, is provided with an oval hole in which various size porcelain insulators can be fitted. Thus different diameter cables can be accommodated between certain minimum and maximum limits. The insulator is constructed slightly thicker at the top and bottom than at the sides to prevent breakage when the clamp is tightened.

BUS SUPPORT MADE ADJUSTABLE TO FIT SEVERAL SIZES OF CABLE

The tapered joint between the insulator sections permits considerable adjustment and allows for creepage of the cable. The part holding the insulator sections can be moved freely about an axis perpendicular to the bottom clamp, but is held in any desired position by

means of a cap-screw shown in the diagram. All of the insulators are tested with two and one-half to five times actual working voltage for dielectric strength.

Transformers for Industrial Plant Illumination

The Bay Point Electrical Supply Company of Berkeley, Cal., is marketing a line of auto-transformers especially adapted for use in industrial plants. The auto-transformer changes the potential from 440 volts, the pressure usually carried on industrial-plant power circuits, to 220 or 110 volts for the lighting circuits. The transformers are made in single-phase and three-phase units, and for large sizes they are oil-cooled. In capacities of under 7500 kva. they are air-cooled.

Cam-Driven Electric Pump

A double-acting cam-driven electric pump manufactured by the Luitweiler Pumping Engine Company of Rochester, N. Y., is shown in the accompany-

DOUBLE-ACTION PUMP CAN BE SUSPENDED BY CHAIN OR PLACED ON ANY FLOOR

ing illustration. The double-acting feature equalizes the load pressure upon the camshaft bearings at all stages of the cycle. The absence of water-load friction in the camshaft bearings is a particular feature of the pump. The pump is geared directly to a motor on the same base and operates with practically no vibration at speeds of 75 to 250 r.p.m. when unattached to the floor. It can also be operated when hanging suspended from chains or when supported on rollers without showing vibration. The driving mechanism is inclosed within a metal case and is lubricated by the splash system.

Direct Lighting Non-Glare Piano Lamp

A piano lamp that has the advantage of direct lighting and produces no objectionable glare is being manufactured by the Play-O-Lite Company, Inc., of Buffalo, N. Y. The hood is so constructed that the light rays are released only in a downward direction so as to fall upon the music rack and the entire keyboard. The "Play-O-Lite" piano lamp is made of metal and can be finished to harmonize with the woodwork of any piano. It can be easily attached to the piano and will not scratch it, because all exposed surfaces are covered

with felt. The socket is of the pull-chain type and is detachable so that the bulb can be replaced at will. Another advantage that the piano lamp has is that it may be quickly removed from the piano and attached to a bed for reading after retiring.

Flexible Metallic Packing

The Crane Packing Company, 29 South Clinton Street, Chicago, is marketing a flexible and compressible packing that is made of long, thin, continuous strips of metal foil and wrapping. Each strip is lubricated with oil which impregnates the sheet and permits it to slide on the adjoining strips. This construction also permits bending the packing around small-diameter bodies and gives it a compressibility sufficient to compensate for wear. It is claimed by the manufacturer that these spirally wrapped sheets form perfect barriers through which steam cannot penetrate. It is also said that this packing will reduce the rod friction and wear on the packing.

"Daylight" Glass for Reflectors and Shades

The Laco-Philips Company of 131 Hudson Street, New York City, has placed upon the market a glass product under the trade name of "Laco-daylite," which, it claims, will permit correct determination of color values. It is made by chemically treating plain glass and is made to fit standard sizes and shapes of all reflectors on the market. It is equipped with holders permitting it to be easily attached to any reflector. The advantage of this glass lies in the fact that it can be used for display purposes in department stores, and for industrial lighting where color values or accurate measurements are required.

Centrifugal Pump with End Suction

A new design of centrifugal pump manufactured by the Wheeler Condenser & Engineering Company, Carteret, N. J., is illustrated herewith. The pump is interesting because of the posi-

END-SUCTION CENTRIFUGAL PUMP THAT OCCUPIES SMALL SPACE

tion of the suction opening, which is directly below and in line with the end bearing. This arrangement, it is pointed out, makes it possible to place the pumping unit in a small room. Furthermore, it is convenient for inspection and upkeep.

Trade Notes

Changes in Western Electric Company's Staff

The following changes in the staff of the Western Electric Company of New York City have been announced:

G. T. MARCHMART, who has been assistant sales manager of the house at Richmond, Va., for the last four years, is now sales manager.

J. H. SYMONDS, for nearly twenty years in the service of the company, is the new stores manager at Minneapolis, Minn., where he has been for four years past.

R. A. GRIFFIN, for fourteen years manager of the pole department, on April 1 became vice-president of the National Pole Company of Spokane, Wash., with headquarters in New York.

W. P. HOAGLAND, who has been appointed sales manager of the company's Chicago house, has been connected with that branch since 1900, having been head of the supply sales work for the last seven years.

WILLIAM F. BANCKER on April 1 was made general purchasing agent of the company in New York City. He has been with the concern since 1899. C. A. Merrill, who also dates his connection with the company from that year, was promoted to be assistant general purchasing agent at the same time.

CLARK H. MINOR, whose connection with the company dates from 1902, he having been successively manager of the Kansas City (Mo.) and Omaha (Nebr.) branches and more recently at Antwerp, Belgium, has been assigned to special work in China and Japan. Mr. Minor will report to G. Swope, vice-president and general sales manager in the New York City office.

HOWARD W. HALL has been transferred from Richmond, Va., to Atlanta, Ga., where he becomes Southern district manager. Mr. Hall has been with the company since 1901 and in 1906 was made manager at St. Louis, Mo., later going to Nashville, Tenn., and Denver, Col. Jay B. Odell, who has been with the company in New York City since 1904, succeeds Mr. Hall in Richmond.

GEORGE M. DUNN, manager of the company's Pittsburgh house since 1913, has been made manager at Philadelphia, succeeding Jerome D. Kennedy, who takes charge of the general sales department at Hawthorne, Ill., with the title of assistant contract sales manager. Mr. Kennedy's services with the Western Electric Company began in 1899 as an engineer in New York City. Joseph L. Ray takes Mr. Dunn's position in Pittsburgh, where he has been sales manager since 1913.

FRED B. GLEASON, for the last sixteen months Southern district manager of the company, with headquarters in Atlanta, Ga., comes to New York City as contract sales manager. He has been with the company since 1904, was manager at Dallas, Tex., four years later went to San Francisco and then to Japan, where he was Far Eastern manager. Henry L. Grant also comes to New York from Chicago for special work in the sales department. He has been with the company in various important capacities since 1905.

THE GOODYEAR TIRE & RUBBER COMPANY of Canada, Ltd., has removed its office from Toronto to New Toronto.

THE SOUTHERN CORPORATION, engineer, 40 Exchange Place, New York, announces that it has closed its office, at least for the period of the war.

THE ELECTRICAL ENGINEERS' EQUIPMENT COMPANY of Chicago on April 4 gave a dinner to seventy-five of its employees and their wives, after which the entire party went in a body to hear "Billy" Sunday speak at his Lakeside Tabernacle.

ROBERT S. BLAKE, formerly connected with the Condit Electric & Manufacturing Company of Boston, as its Pittsburgh (Pa.) representative, is now district manager for the Duquesne Electric & Manufacturing Company in its Chicago office at 230 South LaSalle Street.

THE GENERAL INSULATOR COMPANY of Brooklyn, N. Y., which some years ago inaugurated a bonus system among its employees that has produced excellent results, has now gone a step further and become a co-operative concern. Henceforth all employees of the company will participate in its net earnings.

THE SCHROEDER HEADLIGHT COMPANY of Evansville, Ind., has acquired control of the L. R. Jones Company of Kansas City, Mo., and will consolidate the two concerns at the former place. R. B. Holliday, formerly with the Worthington company at Milwaukee, Wis., will be the new superintendent, and E. D. Goodell, representing the Toledo (Ohio) Sales Company in Cleveland, Ohio, will be the sales manager.

THE BINDER ELEVATOR & ELECTRICAL COMPANY of Birmingham, Ala., has removed its offices from the plant and warehouse, 209-211 Twenty-second Street, North, to 305 Twentieth Street, North, where a new store has been opened. All office work for the plant, construction department and retail establishment will be handled at the Twentieth Street address, while the old building will be devoted exclusively to the electrical repairing, motor and elevator work.

THE GILHAM-SCHOEN ELECTRIC COMPANY, INC., is opening an electrical jobbing house in Atlanta, Ga., at 22 Luckie Street. The company consists of P. C. Gilham, who has been associated with the electrical jobbing interests in the South for many years, being connected with the Western Electric Company and Carter Electric Company of Atlanta, and George F. Schoen, who has since 1902 acted in the capacity of a manufacturers' agent. The company expects to be ready for business by June 1.

Trade Publications

LAMP CHANGERS.—W. N. Matthews & Brothers, Inc., of St. Louis, Mo., are distributing a circular describing their easy lamp changer and the "Fuswitch."

SHADE ATTACHMENT.—An attachment for holding two-unit shades is described in a folder issued by the E. W. Ham Electric Company, Worcester, Mass.

SWITCH PLATE.—Bulletin 574, issued by the Peerless Light Company, Halsted, Adams and Green Streets, Chicago, illustrates its combination switch and receptacle plate.

FACE AND HAND DRIER.—The Groton Electrical Devices, Inc., Groton, N. Y., is distributing a circular describing its "Airdry" electrical drier. The circular illustrates the method of drying the hands and face with the device.

FORGE BLOWERS.—Roth Brothers & Company, Adams and Loomis Streets, Chicago, are distributing a circular describing the Rothmotor forge blowers. Other electrically operated machines are also illustrated in the circular.

SPRAY-HEADS.—The Yarnall-Waring Company, Chestnut Hill, Philadelphia, has issued Bulletin No. N601, describing its adjustable spray-heads for cooling tanks. The construction and operation of the spray-heads are outlined in the bulletin.

MARINE FITTINGS.—This is the title of a circular being distributed by the V. V. Fittings Company of 1910 North Sixth Street, Philadelphia, describing its vapor-proof marine fittings for shipbuilding purposes. The bulletin shows the complete line of standardized parts.

ELECTRIC ELEVATORS.—The Indiana State Soldiers and Sailors' Monument at Indianapolis, Ind., is illustrated in a circular distributed by the Warner Elevator Manufacturing Company of Cincinnati, Ohio. The balcony, which is 228.5 ft. above the ground, is reached by a Warner electric elevator.

RECTIFIERS, INSTRUMENTS AND CONTROLLERS.—The General Electric Company of Schenectady, N. Y., has issued several bulletins describing its "Tungar" rectifier for public garage and battery-charging stations, miniature direct-current instruments and drum-type controllers for railway service.

AUTOMOBILE LAMPS.—A "National Guide to Proper Lamps for Gasoline Passenger Automobiles" is the title of a booklet being distributed by the Electric Appliance Company, Chicago. Tables are presented which give the proper lamps for all cars manufactured in the United States from 1914 to 1918.

BUS SUPPORTS.—This is the title of a bulletin distributed by Lewis & Roth Company of Philadelphia, describing and illustrating a line of bus supports. The bus supports are made adjustable to accommodate various cable sizes within specified minimum and maximum limits, and are equipped with adjustable bases.

ELECTRICAL APPLIANCE CODE.—A code for construction and tests of electrical appliances has been issued by the National Board of Fire Underwriters, 207 East Ohio Street, Chicago. The book gives general information concerning the Underwriters' Laboratory and its organization, including the electrical council, the industry council and methods of procedure in examining, testing and reporting upon electrical appliances. Codes are given for wires, conduits, armature cables, cartridge fuses, map switches, cable and cut-out boxes, signs, panelboards, knife switches, cut-out bases and lugs. The book is bound in a loose-leaf leather binding and is designated as volume one.

New Incorporations

THE SPEED ELECTRIC COMPANY of Poplar, Mont., has been incorporated with a capital stock of \$10,000 by M. A. Erickson and others.

THE JEFFERSON (KY.) LIGHT & POWER COMPANY has been chartered by G. E. Maddy, Fred Bobeck and R. V. Cowger. The company is capitalized at \$2,000.

THE AL-CO OIL, GAS & ELECTRIC COMPANY of Aline, Okla., has been incorporated with a capital stock of \$100,000 by L. J. Dixon, L. H. Stephens and I. A. O'Shaughnessy.

THE IRVINE (KY.) ELECTRIC LIGHT COMPANY has been incorporated with a capital stock of \$80,000. The incorporators are: John J. Langan, Minnie Langan and J. Floyd Rogers.

THE MINGO COUNTY UTILITIES COMPANY of Williamson, W. Va., has been incorporated with a capital stock of \$5,000. The incorporators are: S. G. Kilburn and others.

THE LEONE DUAL LIGHTING & IRRIGATION COMPANY of Seattle, Wash., has been incorporated with a capital stock of \$50,000 by C. P. Gorman, J. G. Brown and W. H. Angel.

THE NORTH McDONOUGH LIGHT & POWER COMPANY of Good Hope, Ill., has been incorporated by J. E. Lowe, Alvah Allison and G. W. Staph. The company is capitalized at \$10,000.

THE AUTOMATIC CHANGEABLE ELECTRIC SIGN COMPANY of Gettysburg, Pa., has been chartered with a capital stock of \$5,000 to manufacture electric signs. H. L. Snyder is treasurer.

THE APPLIANCE SALES COMPANY of Williamsport, Pa., has been incorporated with a capital stock of \$9,000 to manufacture electrical appliances, etc. J. P. Haag of Williamsport is interested in the company.

THE J. L. BERTSCH COMPANY of Boston, Mass., has been incorporated by J. L. Bertsch, R. B. Walsh and J. J. Murphy. The company is capitalized at \$15,000 and proposes to manufacture electric and gas fixtures.

THE MICHIGAN VALLEY LIGHT CORPORATION of Grand Rapids and Detroit, Mich., has been chartered with a capital stock of \$40,000 by R. H. Williams of Detroit, R. E. Becker and Thad Manning of Grand Rapids.

THE INTERNATIONAL ELECTRIC COMPANY of Indianapolis, Ind., has been chartered by Gordon B. Tanner, Fred Sterling, Jr., and M. H. Tanner. The company is capitalized at \$20,000 and proposes to manufacture electrical machinery.

THE PENN MILLS, JEFFERSON, AND BERNVILLE LIGHT, HEAT & POWER COMPANIES of Bernville, Berks County, Pa., have been granted charters. Each company is capitalized at \$5,000. William Kalbach is treasurer of all the companies.

THE GALENA (MD.) ELECTRIC LIGHT & POWER COMPANY has been incorporated by Allison P. and Raymond Prettyman, Lawrence R. Vansant, James D. Davis, Harry A. Bolton and Harry S. Dempsey. The company is capitalized at \$10,000.

THE DYNAMO & MOTOR EXCHANGE, INC., of Buffalo, N. Y., has been incorporated by Frank Martin, John H. Farrell and Albert J. Bissonette, 314 Wyoming Avenue. The company is capitalized at \$10,000 and proposes to deal in dynamos, electrical equipment, etc.

THE MILFORD (N. H.) COMPANY has filed articles of incorporation with a capital stock of \$5,000,000 for the purpose of building a hydroelectric power plant in the southern part of New Hampshire. The incorporators are: Joseph C. Donovan, J. Edward Flynn, Peter J. King and Robert Upton, all of Concord.

New England States

RUMFORD, ME.—Work has begun on the construction of a plant to manufacture ferrosilicon in Rumford. The company has entered into a contract with the Rumford Falls Power Company for 3000 hp. (electrical) to operate the proposed plant. Dudley Harde of New York, N. Y., is promoter of the project.

GOFFSTOWN, N. H.—The Manchester (N. H.) Traction, Light & Power Company has begun work on the construction of its new power house and dam in the Greggs Falls district at Goffstown. French & Hubbard, 88 Pearl Street, Boston, Mass., are engineers.

BRATTLEBORO, VT.—The Village Commissioners are considering a proposal submitted by the Twin State Gas & Electric Company for installing a new street-lighting system. The company offers to remove the arches of 20-cp. lamps and the 100-cp. lamps on poles now in use and to substitute 250-cp. lamps.

MIDDLEBURY, VT.—Plans are being prepared by the Horton Power Company of Rutland for the construction of a new power house, 25 ft. by 90 ft., at Middlebury. Grover & Connor of Rutland are engineers.

BOSTON, MASS.—Plans have been prepared by the Bureau of Yards and Docks, Navy Department, Washington, D. C., for the construction of a new power plant at the local navy yard, to cost about \$35,000.

CAMBRIDGE, MASS.—The Cambridge Electric Light Company has awarded contract for the construction of addition to its boiler plant to the John F. Griffin Company, 17 Milk Street, Boston, Mass. The cost is estimated at about \$20,000.

LEE, MASS.—The Pittsfield Electric Company has taken over the control of the Lee Electric Company. No change, it is understood, will be made in the local service at present.

SHERBORN, MASS.—Bids will soon be asked by the Director of Prisons, State House, Boston, for the construction of a central heating plant in the Sherborn Reformatory, to cost about \$63,000. The proposed work will include power house, tunnel for pipes, etc. The R. D. Kimball Company, 6 Beacon Street, Boston, is engineer.

WESTFIELD, MASS.—At a special town meeting held April 8 the citizens voted to close down the municipal electric generating plant and to purchase energy to operate the local system from the Turners Falls Power & Electric Company. The town also voted to appropriate \$42,000 to purchase the necessary equipment to enable the Municipal Light Department to utilize power from the Turners Falls plant.

HARTFORD, CONN.—The Arrow Electric Company is contemplating the construction of an addition, 80 ft. by 125 ft., three stories, to its plant, and also a concrete coal pocket, 35 ft. by 60 ft.

NORWICH, CONN.—The Eastern Connecticut Power Company has acquired what is known as the Rogers farm at Browning Beach, on which, it is said, it will erect a large power plant immediately. This is the power plant which the company is reported to have intended to build at Thamesville.

NORTH GROSVENOR DALE, CONN.—Contract has been awarded by the Grosvenor Dale Company to the J. W. Bishop Company of Worcester, Mass., for alterations in its power house, to cost about \$35,000.

Middle Atlantic States

ALBANY, N. Y.—Bids will be received by Dr. Herman M. Biggs, commissioner of health, Department of Health, Albany, until May 8, for heating, sanitary and electric work for the Laboratory Building, Division of Laboratories, State Department of Health. Drawings and specifications may be consulted at the New York office of the Department of Architecture, Room 1224, Woolworth Building, and at the Department of Architecture, Capitol, Albany. Lewis F. Pilcher is state architect.

COOPERSTOWN, N. Y.—The Southern New York Power & Railway Corporation has petitioned the Public Service Commission for authority to execute a first mortgage to the Equitable Trust Company of New York as trustee, to secure an issue of \$5,000,000 in bonds. Also for an amendment to a prior order of the commission to authorize the immediate issue of \$952,000 in bonds in exchange for outstanding bonds and the issue of \$48,000 additional bonds upon the acquisition of a like amount of the capital stock of the Southern New York Power Company. The remaining \$4,000,000 in bonds is to be issued from time to time

Construction

News of Projects, Plans, Bids and Contracts. Notes on Work Under Way

for the acquisition of additional property and for extensions and improvements to its system.

CORTLAND, N. Y.—Plans have been filed by the New York Telephone Company for the erection of an addition to its local exchange building, to cost about \$25,000. The contract for the work has been awarded to the Pulford & Dempsey Construction Company, 157 Flack Street, Elmira.

GLENS FALLS, N. Y.—Plans are under consideration by the Adirondack Power Company for the construction of a new power station near Utica.

OGDENSBURG, N. Y.—The local power house of the New Jersey Zinc Company was recently destroyed by fire, causing a loss of about \$300,000. Plans are being considered by the company for rebuilding the plant immediately.

PORT CHESTER, N. Y.—Contract has been awarded by the Liberty Electric Corporation for the construction of an addition to its plant, 60 ft. by 100 ft., one story high, to cost about \$8,000.

SCHENECTADY, N. Y.—Contract has been awarded by the General Electric Company to the Austin Company, Euclid Avenue, Cleveland, Ohio, for the construction of a 300-ft. extension to its plant.

YONKERS, N. Y.—Contract has been awarded by the National Sugar Refining Company, foot of Main Street, for addition to its boiler plant to Lynch & Larkin, 127 Downing Street, Yonkers. The building will be about 85 ft. by 95 ft., and will cost about \$40,000.

CAPE MAY C. H., N. J.—The Board of Utility Commissioners has issued notice to the Vulcan Heat, Light & Power Company to continue service to customers already connected with its system; also to make improvements to the equipment in its plant.

ELIZABETHPORT, N. J.—Contract has been awarded by the Singer Manufacturing Company, 149 Broadway, N. Y., to the Austin Company, Bulletin Building, Philadelphia, for the construction of an addition, 200 ft. by 600 ft., to its works at Elizabethport, to cost about \$300,000.

PERTH AMBOY, N. J.—The Public Service Electric Company has recently completed the installation of new equipment, consisting of a new exhaust steam condenser, having a cooling surface of 16,500 sq. ft., a 10,000-kw. turbo-generator and auxiliary apparatus. The company, it is said, is planning further extensions to the plant.

WEST ORANGE, N. J.—Plans have been filed and contract awarded by Thomas A. Edison, Inc., Lakeside Avenue, to the Underpinning & Foundation Company, 290 Broadway, New York City, for the construction of foundations and superstructure for a new power house, 100 ft. by 100 ft., one story high.

BRISTOL, PA.—The Town Council is considering changing the motive power of the municipal pumping station from steam to electricity.

ERIE, PA.—Bids will be received by the Board of Education, Erie, until April 29 for general work, heating, plumbing and electric work for the new East High School shop wing. Plans and further information may be obtained on application to the board at Erie or to William B. Ittner, architect, St. Louis, Mo.

MAUCH CHUNK, PA.—Plans are under consideration by the Town Council for improvements to the electric street-lighting system.

MIDDLETOWN, PA.—The War Department is contemplating the construction of a new ordnance plant at Middletown, near Harrisburg. The plans provide for the erection of 30 buildings.

NEW CASTLE, PA.—The South New Castle Electric Company, recently incorporated with a capital stock of \$5,000, proposes to operate an electric plant in New Castle. J. C. Chesnut is interested in the company.

NEW CASTLE, PA.—The Grasdelli Powder Company of Cleveland, Ohio, is contemplating the construction of a new powder plant in New Castle. The proposed plant will cost about \$750,000 and will consist of eight individual units, with power plant.

PHILADELPHIA, PA.—Plans are being considered by Hugo Bilgram, 1217-33 Spring

Street, for the construction of a new machine shop, to cost about \$100,000.

PHILADELPHIA, PA.—Contract has been awarded by the George W. Smith Company, Forty-ninth and Botanic Avenues, to John N. Gill & Company, Otis Building, Philadelphia, for the construction of an addition to its boiler house, to cost about \$35,000.

PHILADELPHIA, PA.—The contract for electrical work in connection with the new school building now being erected at Fifty-seventh and Haverford Avenues has been awarded to James F. Buchanan Company, 1719 Chestnut Street. The cost of the building is estimated at \$113,000.

PHILADELPHIA, PA.—Bids will be received at the Bureau of Yards and Docks, Navy Department, Washington, D. C., until April 22 under specification 2867 for furnishing three electrically operated traveling cranes for air craft factory. Extension of date from March 28. The cost is estimated at \$56,000.

PHILADELPHIA, PA.—The Louis Walther Manufacturing Company, Torresdale Avenue and N Street, has awarded contract for erection of addition to its boiler plant and other improvements to George H. Thirsk, 1919 West Berks Street, Philadelphia. The cost of the entire work is estimated at \$21,000.

PHILADELPHIA, PA.—Tentative plans have been prepared for generating electrical power at the mines and transmission of same to Philadelphia, New York and other cities. The proposed plans provide for extension of some of the plants as soon as possible at the mines to develop at least 100,000 hp. as the first step. The second step will be to construct two or three plants of 100,000 kw. capacity. It is proposed to connect with the transmission lines of the Philadelphia Electric Company and those of the Public Service Corporation of New Jersey. The plan also embraces a proposal to connect with the lines of the large power stations in New York and Newark. Nothing definite has yet been decided upon. William Potter, state fuel administrator, Charles E. Stuart, public utility engineer of the fuel administration, S. Z. Mitchell and R. J. McClelland of New York, N. Y., are interested in the project.

READING, PA.—The Metropolitan Edison Company has begun work on the extension of its transmission line to the mine of the E. & G. Brooke Iron Company at Birdsboro, a distance of 6 miles. The company has recently equipped the mine for electrical operation and will require about 500 hp.

BALTIMORE, MD.—Plans have been submitted by the Consolidated Gas, Electric Light & Power Company to contractors for estimates for the construction of an additional unit at its Westport plant. The plans call for a building, 220 ft. by 100 ft., four stories, of concrete and steel construction.

ALEXANDER, VA.—Contract has been awarded by the American Shipbuilding Company of Alexandria, recently incorporated with a capital stock of \$10,000,000, for the erection of its proposed shipbuilding plant at Jones Point, on the Potomac River, near Alexandria. The present plans provide for six shipways, a steel fabricating plant, 200 ft. by 400 ft., and a machine shop, 75 ft. by 200 ft. Colon H. Livingstone of Washington is president.

WILLIAMSBURG, VA.—The capital stock of the Williamsburg Power Company has been increased from \$25,000 to \$150,000, the proceeds to be used for extensions and improvements.

WASHINGTON, D. C.—Contract has been awarded by the War Department, Washington, amounting to about \$800,000, for airplane works at Montgomery, Ala., West Point and Americus, Ga. The total cost of the plants is estimated at over \$2,000,000. They will consist of assembling and repair work shops, including machine, foundry and other shops.

WASHINGTON, D. C.—Bids will be received at the Bureau of Supplies and Accounts, Washington, D. C., for furnishing at the various navy yards and naval stations supplies as follows: Puget Sound, Wash., Schedule 1774—205,000 ft. rubber-insulated lighting and power wire, 600 volts and less. Mare Island, Cal., Schedule 1776—100 yards plain muslin insulating tape. Various, Schedule 1771—121 electrically driven, 110 and 120-volt sewing machines. Applications for proposal blanks should designate the schedule desired by number.

WASHINGTON, D. C.—The War Department, it is reported, is considering the construction of additional nitrate plants, involving an expenditure of \$500,000,000, in addition to the \$30,000,000 and \$5,000,000 plants at Muscle Shoals. One of these plants, it is understood, will be erected at

or near Lock Twelve on Warrior River and another at Kingsport, Tenn. The cyanamid process will be used. Electricity will be obtained from the Alabama Power Company of Birmingham, Ala., for the plant at Kingsport, and the Georgia Power Company of Atlanta, Ga., for the Lock Twelve plant.

WASHINGTON, D. C.—Bids will be received by the Bureau of Supplies and Accounts, Navy Department, Washington, D. C., until April 22, for furnishing at the various navy yards and naval stations supplies as follows: Eastern navy yards, Schedule 1010½—portable electric hand lanterns. Mare Island, Cal., Schedule 4015½—5000 ft. telephone cable and a miscellaneous quantity of electric cable; Schedule 1075½—3719 ft. three-conductor cable. Brooklyn, N. Y., Schedule 1027½—20 electrically driven winches; Schedule 4076½—20,000 ft. electric wire. Washington, D. C., Schedule 1072½—telephone cable. Bids will be received also until April 22 as follows: Washington, D. C., Schedule 4023½—for 20 motor-driven lathes. Mare Island, Cal., Schedule 4034½—magnet wire, 22,000 ft. rubber-insulated lighting and power wire, 200 lb. slow-burning wire, 2000 ft. lighting and power wire, 700 ft. switchboard cable and 1600 ft. ignition copper cable. Eastern navy yards, Schedule 4045½—battery charging panels. Eastern and Western navy yards, Schedule 4050½—2000 turret lighting fixtures and 1000 magazine lighting fixtures. Washington, D. C., and Brooklyn, N. Y., Schedule 4083—eight reels antenna wire, 600 ft. each, for Brooklyn and 100 radio spark transmitters. Charleston, Mare Island and Philadelphia, Schedule 4088½—3850 lb. brass tubes and sheet copper. Philadelphia, Pa., Schedule 4089½—electrical supplies. Bids will also be received until May 3 for the following supplies: Washington, D. C., Schedule 4098½—for four electric centrifugal machines. Applications for proposals should designate the schedule desired by number.

North Central States

CHARLEVOIX, MICH.—At an election held recently the proposal to issue \$55,000 in bonds to purchase the hydroelectric plant at Bellaire was carried.

ONSTEAD, MICH.—A new electric-light plant has recently been installed in Onstead.

CINCINNATI, OHIO.—The plant of the Hamilton & Rossille Company, west of North Front Street, will be removed from its present site in Cincinnati to the Baltimore & Ohio Railroad Company. The company, which formerly furnished water power, is planning to supply electricity in the near future.

CLEVELAND, OHIO.—Plans are being considered by the Cleveland Hardware Company for the construction of an addition, 40 ft. by 200 ft., to its machine shop.

SALEM, OHIO.—The Salem Lighting Company, which has been constructing a large addition to the local electric power plant and erecting a high-tension transmission line to supply energy to the plant of the Morgan Engineering Company in Alliance, 14 miles distant, it is reported, has received instructions from Washington to cease the work. A large part of the addition has been built and several miles of poles set between here and Alliance.

SAVANNAH, OHIO.—The local electric-light plant, town hall and a number of other buildings were recently destroyed by fire. The total loss in estimated at about \$50,000.

TROY, OHIO.—The electrical plant, owned by Hobart Brothers, was recently destroyed by fire, causing a loss of about \$10,000.

MOUNT OLIVET, KY.—The Mount Olivet Electric Light & Power Company is contemplating the installation of either a storage battery or a smaller (15-hp.) engine and a 10-kw., 220-volt direct-current generator. Joseph H. Kain is owner.

WHITESBURG, KY.—The Powell Coal Company, recently organized with a capital stock of \$300,000, has leased several thousand acres of coal land which it will develop. The plans provide for the installation of an electrically driven plant and establishing a town site, to cost about \$500,000. Charles Powell, Louisville, president.

INDIANA HARBOR, IND.—Contract has been awarded by the Standard Forging Company, East Jackson Street, Chicago, Ill., for construction of a new engine house and other buildings at Indiana Harbor, to cost about \$15,000.

HARRISBURG, ILL.—The Southern Illinois Light & Power Company has been granted permission by the Public Utilities Commission to issue \$94,300 in bonds.

MATTOON, ILL.—The Public Utilities Commission has authorized the Central Illinois Public Service Company to issue \$75,000 in gold notes.

APPLETON, WIS.—The Standard Manufacturing Company is planning to erect a new factory building, 120 ft. by 120 ft., to cost about \$75,000. New equipment, including electric motors, etc., is being purchased.

MILWAUKEE, WIS.—A brick and steel forge shop, 150 ft. by 200 ft. and 175 ft. high, for the production of propulsion shafts for government shipbuilding, is being erected by the Allis-Chalmers Manufacturing Company. The new shop is being built around the present forge shop. An 80-ton electric traveling crane with a runway of 200 ft. will be installed.

SHEBOYGAN, WIS.—Plans are being prepared by Juhl & Smith, architects, for a new power house, machine shop and garage, 76 ft. by 130 ft., for the Badger State Tanning Company. Bids for the work, it is understood, will soon be asked.

MINNEAPOLIS, MINN.—Contracts will soon be awarded by J. C. Thompson, 118 North Broadway, for construction of garage and machine shop, 66 ft. by 140 ft., to cost about \$35,000.

NORWOOD, MINN.—Arrangements are being made by the Northern States Power Company of Chicago, Ill., to supply electrical service in the town of Norwood. The local municipal gas plant has been ordered closed down by the state fire marshal.

FARGO, N. D.—The City Commission has authorized J. J. Jordan, city engineer, to prepare estimates of the cost of installing an electric light plant at the municipal waterworks station for lighting the city streets. The city attorney has also been instructed to draw a bill to be presented in the next State Legislature empowering cities to own and operate municipal electric-light, heat and power plants and to sell direct to consumers. Under the present law cities can only operate lighting plants.

ABERDEEN, S. D.—Bids will be received by W. E. Johnson, president of the regents of education of the State of South Dakota, Aberdeen, until April 27 for construction of Lincoln Hall on the grounds of the Northern Normal and Industrial School, Aberdeen, including arcade, boiler house, lighting fixtures, etc. Plans and specifications are on file in the office of George F. Foster, architect, Aberdeen.

SIoux FALLS, S. D.—The contract for electric wiring for parish house and sacristies of the Sioux Falls cathedral has been awarded to the Olsen-Boettger Electric Manufacturing Company, 413 North Franklin Street, St. Paul.

Southern States

OLDSMAR, FLA.—The Oldsmar Electric & Ice Company, recently organized, contemplates the installation of an electric-light plant and ice factory. Jacob Bornstein is president.

KINGSFORT, TENN.—Arrangements are being made by the War Department, Washington, D. C., for the construction of a nitrate plant on a 2000-acre site on the Carolina, Clinchfield & Ohio Railroad and the Kingsport Farms Corporation property, to cost about \$10,000,000.

NASHVILLE, TENN.—The Cumberland Power Company, recently incorporated with a capital stock of \$100,000, proposes to construct and operate an electric plant in Nashville. K. E. Longfield, F. D. Buck and others of Wilmington, Del., are interested in the project.

ALEXANDER CITY, ALA.—At an election held recently the proposal to issue \$10,000 in bonds for improvements to the municipal electric-light plant was carried.

EUFULA, ALA.—Contract has been awarded by the Eufaula Farm Products Company for a fireproof building, to cost about \$40,000. New equipment, including elevator machinery, engine, boiler, feed mill, dryer, peanut sheller, corn shucker and steam plant, will be installed.

CORINTH, MISS.—Bids will be received by the Board of Supervisors of Alcorn County, Corinth, until May 8 for heating, plumbing, lighting and clocks for the new court house, now under construction at Corinth. Plans and specifications may be obtained from N. W. Overstreet, Jackson, upon deposit of \$10.90.

PURVIS, MISS.—The City Council has engaged Xavier A. Kramer, engineer of Magnolia, to prepare plans for the installation of an electric lighting system in Purvis.

HARRISON, ARK.—The Harrison Gas & Electric Company, recently reorganized

with R. M. Fellows, president, is planning to extend the electric-lighting system, and to enlarge the cold storage plant and ice factory.

POWHATAN, I.A.—The Yarbrough Company of Powhatan is contemplating the purchase of Scotch boilers and other power plant equipment.

HARTSHORNE, OKLA.—The Choctaw Power & Light Company of McAlester is contemplating installing an electric-lighting system in Hartshorne.

KIOWA, OKLA.—The Kiowa Ice, Light & Water Company, recently incorporated with a capital stock of \$50,000, it is reported, is planning to install an electric plant and ice factory. L. T. Sammons, Mile T. Crane and others are interested in the company.

PERRY, OKLA.—The Council is considering calling an election to submit the proposal to issue bonds for improvements to the municipal electric-light plant and water-works system.

STILLWATER, OKLA.—Plans have been prepared by H. A. Pressy, engineer, Oklahoma City, for improvements to the municipal electric-light system, to cost about \$30,000. Improvements will be made to the waterworks, involving an expenditure of about \$101,000, and will include four 8-in. three-stage centrifugal pumps, reservoir, filtration plants, etc.

STILLWATER, OKLA.—Bids will be received by F. M. Gault, president of the State Board of Agriculture, Capitol Building, Oklahoma City, until May 2 for construction of science hall and armory-gymnasium building at the Agricultural and Mechanical College. Separate bids to be submitted for heating and plumbing. The general contract includes electrical work, etc. The cost of the building is estimated at about \$200,000. F. W. Redlich of Stillwater is architect.

BREMOND, TEX.—The Calvert (Tex.) Water, Ice & Electric Company is contemplating extending its electric power transmission lines to Bremond and installing an electric distributing system here.

DALLAS, TEX.—Smith & Whitney, 1405 Southwestern Life Building, Dallas, it is reported, would like to receive prices on a 300-kw., 250-volt, two or three-wire, direct-current generating set; engine to be cross compound, non-condensing, non-releasing Corliss type. An engine type generator without engine, but for direct connection to engine of above type, would be considered.

PLEASANTON, TEX.—The City Council has taken over the plant of the Pleasanton Ice & Electric Company and will install additional equipment and machinery.

Pacific and Mountain States

CENTRALIA, WASH.—The City Commission has awarded contract to the Devore Electric Company for furnishing street lamps to the city for one year.

SEATTLE, WASH.—The City Council has granted the National District Telegraph Company a franchise to install and operate a system in Seattle.

SNOHOMISH, WASH.—Among the improvements being made at the plant of the Snohomish Dairy Products Company is the installation of electric motor in several departments. Energy is supplied by the local company. An electric laboratory, with testing appliances, including an electric vacuum oven and computing instruments, has also been installed.

COTTAGE GROVE, ORE.—Machinery has been received by the Cottage Grove Electric Company which, when installed, will double the present output of the plant.

MONDOVI, ORE.—The Washington Water Power Company of Spokane is contemplating extending its electric transmission lines to supply electrical service in Mondovi and surrounding territory.

PORTLAND, ORE.—The Northwestern Electric Company has awarded contract for waterproofing the foundation walls for the power plant under construction in South Portland to the Portland Roofing Company.

FRESNO, CAL.—In order to meet the increasing demands of the oil companies for electrical service in the Kern River field the San Joaquin Light & Power Company is erecting a new substation just east of the Standard reservoir farm. This station will transform current transmitted from the Crane Valley power house district at 60,000 volts to the lower voltage required in the oil field operation. The equipment will consist of four 1000-kva. transformers with necessary switches, etc.

LOS ANGELES, CAL.—Plans and specifications for competitive bids for ornamental

lighting of more than 50 miles of the streets of Los Angeles have been approved by the Board of Public Works. Resolutions have also been submitted for supplying aqueduct power for the ornamental lamps on Broadway from California to Tenth Streets. The Municipal Power Bureau will be awarded this contract as there were no bids submitted when called by the board. The contract amounts to more than \$30,000, as globes and other equipment for the ornamental lighting system on Broadway will be included.

LOS ANGELES, CAL.—Funds to the amount of \$79,000 have been provided by the City Council for the completion of the distribution of municipal hydroelectric power at the harbor. The skeleton of the system, including the high tension feed wires, has been installed, but the money was lacking for installing the laterals and local distributing wires. The Power Department will expend \$34,000 in extending the system to the fish harbor and the balance will be utilized in gridironing the tidelands with service wires. Under a recent order of the Mayor and the Harbor Commission none but municipal power can be used at the harbor.

PASADENA, CAL.—The City Commission has approved the proposed contract with the Southern California Power Company whereby the city of Pasadena will lease the distributing system of the Edison company for a period of two years, with the privilege of buying it at the expiration of the contract. If approved by the State Railroad Commission the contract will become effective May 3.

RIALTO, CAL.—The Railroad Commission has granted the Rialto Light, Power & Water Company permission to sell its properties to the Southern Sierras Power Company for \$25,734. The Rialto Company furnishes electricity in and about Rialto. The Southern Sierras Power Company has joined with the Corona (Cal.) Gas & Electric Company, the Bishop (Cal.) Light & Power Company, the Coachella (Cal.) Valley Ice & Electric Company and the Rialto Company for authority for the Southern Sierras Power Company to purchase the last four corporations.

SAN FRANCISCO, CAL.—An agreement has been reached under which the Pacific Gas & Electric, the Great Western Power and the Sierra & San Francisco companies have consolidated (as a war measure) to operate their electric plants, both steam and hydroelectric, under one head. It was made

primarily for the purpose of conserving fuel oil and has the sanction of the State Railroad Commission and will last for the period of the war.

WESTON, UTAH.—Application has been made by the citizens of Weston to the Public Utilities Commission asking for an extension of the service lines of the Utah Power & Light Company to Weston. The town is at present without electrical service. A 5-mile extension of the Utah Company's line would be necessary, the cost of which is estimated at \$16,000.

LUSK, WYO.—Contract has been awarded by the town of Lusk to the Fairbanks-Morse Company for a 100-hp. semi-Diesel oil engine and a 60-kva., 60-cycle, three-phase, 2300-volt generator (directly connected), and a 50-hp. motor for water works, to be installed in May. L. S. Berry is consulting engineer.

BEOWAWA, NEV.—The electric plant of the Beowawa Electric Light Company has been purchased by the Nevada Valleys Power Company, which owns and operates the plant at Battle Mountain. The equipment of the local plant will be transferred to Battle Mountain and installed in the plant there.

Canada

GLADSTONE, MAN.—The Town Council is considering the installation of an electric distributing system to supply electricity for commercial, domestic and street lighting purposes.

ALVINSTON, ONT.—The project for a hydroelectric development on the Svidenham River, to cost about \$28,000, is being held in abeyance until an effort is made to secure service from hydro system.

HAILEYBURY, ONT.—The Dickson Creek Mining Company is considering the installation of electrically driven drills at its property on Dickson Creek.

HAMILTON, ONT.—E. R. Gray, chief engineer, is preparing a report to be submitted to the Board of Control in connection with the project suggested by T. J. Stewart that the transmission lines of the Toronto & Niagara Power Company be connected up with the Beach pumping station to insure a supply of energy in case of breakdown of the Hydro-Electric service.

OTTAWA, ONT.—Bids will be received by John Pearson and J. O. Marchand, Center Block, Parliament Hill, Ottawa, until April 23, for electric conduit and fittings required in the reconstruction of the Parliament Buildings. Specifications and further information may be obtained at the office of P. Lyall & Sons Construction Company of Ottawa.

TIMMINS, ONT.—A new electric generating unit, consisting of a 3750-kva. Canadian Westinghouse generator with a 4000-hp. Morgan-Smith waterwheel, is being installed in the power plant of the Northern Canada Power Company. E. S. Noble is superintendent.

TORONTO, ONT.—The Hydro-Electric Power Commission has taken over the property of the Essex County Light & Power Company of Leamington, which supplies electrical service in Amherstburg, Kingsville, Essex, Leamington, Harrow, Canard River and Cottam, at \$226,000. The system of the Essex company consists of 55 miles of 26,400-volt transmission lines in addition to distributing systems in the municipalities named and was owned and operated by the Detroit Edison Company of Detroit, Mich.

CHAMBLY, QUE.—The local dam of the Montreal Light, Heat & Power Company was recently carried away by floods.

ARCOLA, SASK.—The Arcola Light & Power Company is contemplating changing its system from single-phase, 110 volts, to three-phase, 2300 volts, and establishing a day service for a power circuit. H. Forbes Robert is manager.

Miscellaneous

PANAMA.—Bids will be received at the office of the general purchasing officer, the Panama Canal, Washington, D. C., until May 2, for furnishing, under circular 1214, sheet and flat steel, marine telegraphs, transformers, electric switches, testing blocks, marine brackets, carbon brushes, condulets, connectors, cut-outs, marine fixtures, plugs, rosettes, steel and copper wire, etc. Further information may be obtained at the above office.

SAN JUAN, HONDURAS.—The iron pipes furnishing water for operating the electric plant at San Juan have been blown up by dynamite. The plants have a daily generating capacity of 7000 hp.

(Issued March 26, 1918.)

1,260,424. COMMON-BATTERY TWO-WIRE REPEATER SYSTEM; Talbot G. Martin, Chicago, Ill. App. filed July 12, 1909. Improvements.

1,260,441. HEATER FOR INTAKE MANIFOLDS OF INTERNAL-COMBUSTION ENGINES; Bert N. Parrish, Jackson, Mich. App. filed May 23, 1917. Heat generated is efficiently transmitted to the walls of the manifold.

1,260,450. ELECTRICALLY CONTROLLED INDICATOR; Earl S. Rau, Elkins Park, Pa. App. filed Nov. 29, 1916. Improved.

1,260,461. FIRE-ALARM-BELL RINGER; Wilton S. Schuyler, Savannah, Mo. App. filed July 7, 1916. Efficient and serviceable.

1,260,463. ALTERNATING-CURRENT RECTIFIER; Ray F. Seitz, Portsmouth, Ohio. App. filed July 3, 1917. For charging storage batteries.

1,260,472. STORAGE-BATTERY ELECTRODE; Thomas Spencer, Philadelphia, Pa. App. filed Aug. 21, 1915. Means for retaining the active material.

1,260,480. ELECTRICAL SYSTEM OF DISTRIBUTION; William A. Turbayne, Niagara Falls, N. Y. App. filed July 8, 1916. Improvements.

1,260,481. ELECTRICAL SYSTEM OF DISTRIBUTION; William A. Turbayne, Niagara Falls, N. Y. App. filed March 8, 1913. Improvements.

1,260,482. ELECTRICAL SYSTEM OF DISTRIBUTION; William A. Turbayne, Niagara Falls, N. Y. App. filed May 27, 1915. Improvements.

1,260,483. ELECTRICAL SYSTEM OF DISTRIBUTION; William A. Turbayne, Niagara Falls, N. Y. App. filed May 27, 1915. Improvements.

1,260,556. AUTOMATIC WEIGHING DEVICE; Frank E. Layman, Milwaukee, Wis. App. filed April 8, 1912. Accurate results when small amounts of material are weighed.

1,260,564. ELECTRIC HEATER; Carl E. Magnusson and Leslie F. Curtis, Seattle, Wash. App. filed Sept. 26, 1917. Induction type.

Record of Electrical Patents

Notes on United States Patents

1,260,591. SNAP SWITCH; Clarence C. Stirling, Hartford, Conn. App. filed June 22, 1917. Improvements.

1,260,592. JUNCTION TERMINAL BLOCK; Guy F. Sturgeon, Chicago, Ill. App. filed Feb. 10, 1915. Improvement.

1,260,607. COMBINATION LOCK SWITCH; Samuel S. Ward, Vienna, S. D. App. filed April 21, 1917. Automobiles.

1,260,613. SYSTEM OF CONTROL; Charles C. Whittaker, Wilkesburg, Pa. App. filed March 4, 1916. For governing the operation of the driving motors of an electric locomotive.

1,260,617. RAILWAY SIGNALING; Henry S. Young, Wilkesburg, Pa. App. filed Dec. 24, 1915. Improvements.

1,260,630. LIGHTNING ARRESTER; Quincy A. Brackett, Pittsburgh, Pa. App. filed June 16, 1916. Outdoor service.

1,260,647. REGULATOR AND CUT-OUT; Frank Conrad, Swissvale, Pa. App. filed April 2, 1913. Automobiles.

1,260,648. ELECTRICAL SYSTEM; Frank Conrad, Pittsburgh, Pa. App. filed Dec. 31, 1913. Controlling the rate at which storage batteries may be charged to correspond to the degree to which the batteries are charged.

1,260,649. REGULATOR AND CUT-OUT; Frank Conrad, Pittsburgh, Pa. App. filed Aug. 7, 1914. Automobiles.

1,260,661. METHOD OF RECOVERING METALS FROM ALLOYS; Julius H. Gillis, Toronto, Ont., Canada. App. filed Sept. 4, 1917. Electrolytic method.

1,260,665. CONTROLLER; Arthur J. Hall, Wilkesburg, Pa. App. filed Dec. 4, 1913. Used with switching apparatus of the rotatable drum type.

1,260,669. CONTROL SYSTEM; Rudolf E. Hellmund, Pittsburgh, Pa. App. filed Oct. 7, 1915. For effecting power-factor corrections.

1,260,666. CONTROL SYSTEM; Arthur J. Hall, Wilkesburg, Pa. App. filed Jan. 5, 1915. Dynamo-electric machines.

1,260,670. DYNAMO-ELECTRIC MACHINE; Rudolf E. Hellmund, Pittsburgh, Pa. App. filed Jan. 5, 1916. Ventilation of heavy-duty motors of the inclosed type.

1,260,674. COIL WEDGE FOR DYNAMO-ELECTRIC MACHINES; Ray P. Jackson, Edgewood Park, Pa. App. filed Jan. 2, 1915. Used in the coil-containing slots.

1,260,675. REGULATOR FOR ELECTRICAL CHARGING SYSTEMS; Edward B. Jacobson, Pittsfield, Mass. App. filed Dec. 3, 1913. Improvements.

1,260,708. ELECTRIC SWITCH CONSTRUCTION; Clarence D. Platt, Bridgeport, Conn. App. filed July 21, 1917. Inclosed type.

1,260,712. STREET AND STATION INDICATOR; Fred B. Robison, Fort Winfield Scott, Cal. App. filed Feb. 6, 1917. Improvements.

1,260,721. CONTROL SYSTEM; Francis H. Shepard, New Rochelle, N. Y. App. filed Dec. 26, 1913. Multiple-unit type.

1,260,729. METAL-FILAMENT LAMP; Johann E. C. Struve, Hamburg, Germany. App. filed March 27, 1914. Represents the contour of letters.

1,260,730. CONTACT MEMBER; Emmett W. Stull, Wilkesburg, Pa. App. filed June 18, 1913. For electrical apparatus.

1,260,742. ELECTRIC INCANDESCENT LAMP; Manfred Aron, Charlottenburg, near Berlin, and Wilhelm Keppel, Berlin, Germany. App. filed Dec. 19, 1913. Improvement.

1,260,715. TRANSFORMER AND METHOD OF MAKING THE SAME; Subo Attila, Frankfurt-on-the-Main, Germany. App. filed July 22, 1909. Adapted for use with metallic filament lamps.

1,260,717. ELECTRIC-ARC LAMP; Frederick R. Boardman, Richard V. Boardman and Frank Boardman, Upton Park, England. App. filed Dec. 17, 1913. Plurality of pairs of carbons.

1,260,750. LIGHTNING ARRESTER; Stanley C. Bryant, Chicago, Ill. App. filed July 21, 1916. Open or exposed air gaps, with the line protected by the arrester not grounded in case the exposed air gaps are bridged or filled with foreign particles.

1,260,785. ROTARY RECTIFIER OF ALTERNATING CURRENT; Constantine D. Macropoulos, New York, N. Y. App. filed Jan. 21, 1914. Eliminates sparking.

1,260,809. CIRCUIT BREAKER; Lewis T. Rhoades, Mont. Chure, Pa. App. filed Sept. 25, 1917. Employs mechanical and magnetic means to interrupt the current through the induction coil.

1,260,819. APPARATUS FOR WINDING COIL CONDENSERS; Wolfgang E. Schwartzmann, Long Meadow, and Charles M. Wild, Springfield, Mass. App. filed May 16, 1916. Improvements.

1,260,830. ELECTROLYTIC DEPOSITION OF COPPER FROM ACID SOLUTIONS; Franz E. Studt, London, England. App. filed July 18, 1916. Improvements.

1,260,843. END PLATE FOR COMBINED IGNITING AND LIGHTING GENERATORS; James M. Wilson, Newark, N. J. App. filed June 30, 1915. Improvements.

1,261,649—Attachment-Plug Receptacle

1,260,853. ELECTRIC LIGHT FIXTURE; Lincoln C. Bair, Kansas City, Mo. App. filed March 26, 1917. Means for suspending bowls of different sizes from the same device.

1,260,875. ELECTRIC ARC WELDING FOR BRAZING; George W. Cravens, Westfield, N. J. App. filed July 23, 1915. Improvements.

1,260,866. BURGLAR ALARM FOR AUTOMOBILES; Thomas F. Burke, Philadelphia, Pa. App. filed June 5, 1917. Improvements.

1,260,889. SYSTEM FOR MOTOR CONTROL; Lionel Fleischmann, Berlin, Germany. App. filed April 16, 1915. Brake which is automatically applied when the motor circuit is opened.

1,260,913. RAIL BOND; Bruce C. Kixmiller, Bicknell, Ind. App. filed May 21, 1917. Electrically connecting.

1,260,930. ALARM SYSTEM; Carl F. Mead and Louis E. Richmond, Cleveland, Ohio. App. filed March 7, 1914. Fire alarm.

1,260,940. APPARATUS FOR WELDING TUNGSTEN INGOTS; Carl A. Pfanstiehl, Waukegan, Ill. App. filed July 12, 1915. Provides an electric furnace.

1,260,971. AUTOMATIC TELEPHONE SYSTEM; Alfred H. Dyson, Chicago, Ill. App. filed Nov. 13, 1906. Improvements.

1,260,982. VOLTMETERS; Frank A. Laws, Salem, and Chester L. Dawes, Cambridge, Mass. App. filed Feb. 6, 1914. Enables extreme points reached by an alternating voltage wave to be indicated and measured.

1,260,985. IGNITION SYSTEM FOR INTERNAL-COMBUSTION ENGINES; Carl T. Mason,

East Orange, N. J. App. filed Sept. 29, 1916. Sparking voltage is furnished by a high-tension magneto.

1,260,989. ELECTRIC ARC WELDING OR BRAZING; George W. Cravens, Garwood, N. J. App. filed July 23, 1915. Improvements.

1,260,994. ELECTRIC REGULATOR; Joseph Bijur, New York, N. Y. App. filed Dec. 1, 1909. Improvements.

1,260,995. ELECTRIC REGULATOR; Joseph Bijur, New York, N. Y. App. filed July 1, 1910. Extreme variation in a resistance element is efficiently utilized.

(Issued April 2, 1918.)

1,261,024. ELECTRIC FIXTURES; Gustav A. Harter, Chicago, Ill. App. filed March 18, 1916. Semi-indirect fixture.

1,261,048. DISTRIBUTOR FOR IGNITION DEVICES; Charles T. Mason, Sumter, S. C. App. filed Sept. 15, 1916. Improvements.

1,261,069. POWER TRANSMISSION; John G. P. Thomas, Chiswick, London, England. App. filed Oct. 11, 1913. Improvements.

1,261,079. GOVERNING DEVICE FOR MAGNETOS; Robert M. Warten, Sumter, S. C. App. filed Feb. 19, 1917. For gas engines.

1,261,086. MEANS FOR REGULATING TEMPERATURE; John C. Wilson and Horace H. Packard, Milwaukee, Wis. App. filed Aug. 16, 1912. Thermal fluid motors.

1,261,091. SAFETY ELECTRIC-CIRCUIT BREAKER FOR AUTOMOBILES; Charles Alcon, Indianapolis, Ind. App. filed Dec. 5, 1916. Means for protecting automobiles and motor-driven vehicles.

1,261,096. TESTING APPARATUS; Otto B. Blackwell, Maplewood, N. J. App. filed Oct. 2, 1916. For determining the transmission losses occurring in electrical transmitting paths.

1,261,102. CENTRIFUGAL SWITCH; Joel R. Cook, Wilkesburg, Pa. App. filed Feb. 17, 1913. For single-phase induction motors.

1,261,126. DYNAMO-ELECTRIC MACHINE; Rudolf E. Hellmund, Pittsburgh, Pa. App. filed April 1, 1915. Magnetizable core members for dynamo-electric machines.

1,261,140. ELECTRICAL BOND FOR RAILWAY RAILS; John C. Lincoln, Cleveland, Ohio. App. filed Feb. 25, 1916. Readily attachable.

1,261,169. CONTROL APPARATUS; Karl A. Simmon and Arthur J. Hall, Wilkesburg, Pa. App. filed April 6, 1914. For dynamo-electric machines and liquid rheostats.

1,261,178. METHOD AND MECHANISM FOR REDUCING RESISTANCE OF AIR GAPS; William W. Strong, Mechanicsburg, Pa. App. filed Jan. 14, 1913. Method of deriving a unidirectional current.

1,261,193. TERMINAL FOR DYNAMOS; Harry R. Van Deventer, Sumter, S. C. App. filed June 10, 1916. Ignition dynamos.

1,261,239. GENERATING SYSTEM AND GENERATOR THEREFOR; Edward B. Jacobson, Pittsfield, Mass. App. filed Nov. 9, 1914. Battery charging.

1,261,250. STREET OR STATION INDICATOR; John O. Lough, Montreal, Quebec, Canada. App. filed March 9, 1917. Improvements.

1,261,251. ELECTRICALLY OPERATED CROSSING SIGNAL; Chester L. Lynch, Seattle, Wash. App. filed Sept. 19, 1916. Improvements.

1,261,256. THERMAL ELECTRIC CUT-OUT; Roy H. Maple, Indianapolis, Ind. App. filed Nov. 20, 1914. For use on low-voltage circuits.

1,261,266. PERMUTATION LOCK FOR AUTOMOBILES; William H. Mitchell, St. Louis, Mo. App. filed Feb. 26, 1917. One permutating-indicating device controls the valve and the switch simultaneously.

1,261,269. BATTERY; William Morrison, Chicago, Ill. App. filed Nov. 2, 1917. Storage battery.

1,261,272. APPARATUS FOR SYNCHRONIZING MUSIC AND MOTION PICTURES; Edward W. Myers, Los Gatos, Cal. App. filed Aug. 21, 1916. Improvement.

1,261,290. TELEGRAPH SYSTEM; Paul M. Rainey, Glen Ridge, N. J. App. filed May 15, 1915. Multiplex telegraphy.

1,261,345. IGNITION APPARATUS FOR INTERNAL-COMBUSTION ENGINES; Joseph Bijur, New York, N. Y. App. filed March 9, 1915. Improved.

1,261,347. ELECTRIC LIGHTING SYSTEM; William L. Bliss, Niagara Falls, N. Y. App. filed Aug. 24, 1912. For use with steam or electrically driven system.

1,261,376. MAGNETIC CONTROLLING DEVICE FOR RAILWAYS; Austen H. Fox and Arnold W. Lenderoth, Stapleton, N. Y. App. filed Nov. 8, 1915. Improvements.

1,261,386. DYNAMO-ELECTRIC MACHINE; Rudolf Hellmund and Charles W. Starker, Pittsburgh, Pa. App. filed Dec. 4, 1914. Internal ventilation during operating condition.

1,261,391. TELEPHONE DIAPHRAGM; Fred Hoyt, Seattle, Wash. App. filed Oct. 25, 1916. Improved means for mounting a vibrating diaphragm in a sound transmitter.

1,261,395. ELECTRODE AS USED FOR WELDING PURPOSES; Malcolm M. Irvine, Glasgow, Scotland. App. filed Sept. 17, 1917. Improvements.

1,261,456. SWITCH; Clarence C. Stirling, Hartford, Conn. App. filed June 22, 1917. Improvements.

1,261,470. INDUCTION WATER HEATER; Charles A. Backstrom, Crafton, Pa. App. filed Sept. 12, 1916. Loss in the return magnetic circuit is utilized for heating the water.

1,261,477. ELECTRIC LIGHTING FIXTURE; George A. Boomer, Waterbury, Conn. App. filed Nov. 22, 1917. Improvement.

1,261,490. APPARATUS FOR RECORDING AND COMPILING STATISTICAL DATA; Wyland B. Clark and Frederick J. Pritchard, Washington, D. C. App. filed June 12, 1916. Improvements.

1,261,492. TELEPHONE SYSTEM; Hiram D. Currier, Richard I. Utter and Michael B. Stazak, Chicago, Ill. App. filed July 27, 1914. Trunking system.

1,261,510. RAILWAY-TRAFFIC-CONTROL APPARATUS; Robert M. Gilson, Pittsburgh, Pa. App. filed Aug. 11, 1916. Improvements.

1,261,677—Circuit Interrupter

1,261,578. ELECTRICAL CONTACT SHOE; William W. MacFarlane, Philadelphia, Pa. App. filed April 20, 1916. Improvements.

1,261,593. STARTER MECHANISM; William Morrison, Chicago, Ill. App. filed Feb. 14, 1916. Double rotor dynamo-electric clutch.

1,261,636. FUSE; Ray Smith, Dayton, Ohio. App. filed March 2, 1917. Fuse elements may be readily replaced.

1,261,644. ELECTRIC MOTOR CONTROL; Walter C. Strang, Yonkers, N. Y. App. filed April 4, 1913. Improved means for slowing down and stopping electric motor.

1,261,649. ATTACHMENT-PLUG RECEPTACLE; George B. Thomas, Bridgeport, Conn. App. filed July 5, 1917. Proper engagement between the jack blades and the receptacle terminals is insured.

1,261,673. ROTOR FOR DYNAMO-ELECTRIC MACHINES; Ernst F. W. Alexanderson, Schenectady, N. Y. App. filed July 28, 1916. High speed.

1,261,677. CIRCUIT INTERRUPTER; Winfield A. Atwood, Schenectady, N. Y. App. filed June 14, 1915. Movable members interconnected by an interlocking device.

1,261,698. BRAKE-OPERATED STOP-SIGNAL SWITCH FOR AUTOMOBILES; Emil Carlson, Pasadena, Cal. App. filed March 8, 1917. Signal apparatus mounted beneath the floor of a motor vehicle.

1,261,708. ELECTRON-DISCHARGE DEVICE; William D. Collidge, New York, N. Y. App. filed June 13, 1916. Improvements.

1,261,711. PROTECTIVE DEVICE; Elmer E. F. Creighton, Schenectady, N. Y. App. filed May 2, 1912. For electric circuits.

1,261,744. ELECTRICAL SWITCHING DEVICE; Arthur O. Dady, New York, N. Y. App. filed April 12, 1916. For ignition circuits of internal-combustion engines.

1,261,745. FIRE-ALARM APPARATUS; Vernon Durbin, Brookline, Mass. App. filed July 25, 1916. Improvements.

Electrical World

The consolidation of ELECTRICAL WORLD, ELECTRICAL ENGINEER and AMERICAN ELECTRICIAN

Volume 71

New York, Saturday, April 27, 1918

Number 17

Service Restrictions on Less Essential Industries

LESS essential industries which find difficulty in procuring coal have in many instances found relief by the adoption of central-station service. This practice is fraught with great danger to public utility interests. While it is the purpose of the Fuel Administration to allow public utilities 100 per cent of their coal requirements, the administration has a right to expect that any policy it may adopt toward non-essential industries will not be thwarted in the manner above indicated. Otherwise, it may be necessary for the government to assume control over the distribution of electricity as well.

Our Great Activity in Manufacturing

TOTALS of a very impressive amount of business are being rolled up in the electrical manufacturing industry. They are the direct result of war activity demanding the largest volume of production from every essential manufacturing resource. Evidence of tremendous gross business which is most conspicuous is that furnished by the General Electric Company through the annual report issued this week. Without war munitions, which entered into the figures of 1915 and to a small extent into 1916, the value of electrical and mechanical orders received in 1917 was \$246,700,000. By comparison with the orders of the same class received in 1916, this represents a gain of 47.6 per cent, and the increase over the corresponding business in 1915 was 150.8 per cent. In other words, the electrical and mechanical orders received in 1917 were two and one-half times those of 1915. The amount of sales billed was of course substantially smaller. But the 1917 total reached the satisfying level of \$196,925,318, representing a gain of 47 per cent over 1916. One qualifying consideration should be kept in mind. That is, that in a period of sharp increase in commodity and labor costs the values mount rapidly. While undoubtedly the increase in quantity of apparatus and supplies is very great, it is not so large as the increase in values in a rising market. In round figures, this one company received orders for \$50,000,000 more than the total sales billed. This is roughly one-quarter of the production capacity represented by sales billed in the whole of last year. In general, the figures are a striking testimony to the unparalleled growth presented by the central stations, which have doubled their output since the European war started four years ago in the summer of 1914.

The Enormous Cost of Niagara as a Spectacle

PROGRESSIVE men on both sides of the Niagara frontier are agreed that even before the war a greater diversion of water from the Niagara River was justifiable and that the present emergency merely changes the word justifiable into obligatory. Sir Adam Beck in his testimony at Washington last week presented an official Canadian viewpoint with reference to Niagara, and an American viewpoint is reflected in this week's issue. It is possible, however, to present the situation very clearly, so that any layman may grasp it. In round numbers, the flow of water and the head at Niagara Falls represent 5,000,000 continuous horsepower. Even at the low price of \$10 a horsepower year, the spectacle has a potential value of \$50,000,000 per annum. Can any nature lover contend that the view is worth any such sum, and would any government be justified in appropriating \$50,000,000 yearly to reproduce the attraction? With these self-evident facts in mind, it is difficult to understand why this profligacy continues, especially when there is such urgent need of the power, a willingness to use more water on both sides of the border, and apparently nothing to stop it except the inertia of governmental bodies. Certainly this inertia is extremely costly; it even borders on the criminal and should be overcome at once.

Higher Rates Will Keep Utilities Strong

IMPARTIAL testimony as to the high value of public utility service to the community and to the nation has been forthcoming recently. The national government through various officials, American business as represented by the Chamber of Commerce of the United States, and regulating bodies such as the Public Service Commission of New York, are agreed that it is in the public interest that the utilities be kept in a condition of solvency and efficiency. This tribute is well merited, deserves to be cherished and to be advertised broadly. It is well known that, owing to constant pressure from commissions, the average price obtained for electricity has steadily diminished all through the era of rising prices that preceded the war and even up to the moment when the United States stood on the brink of hostilities. Even now, with conditions more acute, we have still to hear of a single case of ostentatious shutting down to impress upon the public the gravity of the issue. Not only have the utilities been harassed by increasing prices of all material, of labor and of money,

but added to these has been the uncertainty of the coal situation, and now the losses incident to daylight saving. That measures for relief are imperatively needed is beyond question. The government can very properly lend a hand in securing the necessary capital on reasonable terms, especially where extensions are necessary to meet the calls of war. The companies for their part are spontaneously turning to such economies as are feasible, but no permanent relief is possible without an increase in the price of electricity commensurate with the increased costs of serving the public at this time. Commissioner Whitney's statement, we trust, reflects the opinion of most of the public service commissions. At any rate, it is a good omen. The central-station industry faces a financial crisis which calls for immediate relief.

Stimulating Production by Good Lighting

THE advocates of artificial lighting curtailment as a war measure in industrial plants have received very little encouragement from lighting experts of the country. Those who have studied lighting for years realize that as an aid to rapid and efficient production, accuracy of work, prevention of accidents and keeping up the morale of a force of workers lighting is one of the first things to be considered and that the present cost of good artificial lighting either in dollars or in pounds of coal is very small balanced against loss of production efficiency of the workers due to poor light. These matters have been discussed in these columns repeatedly of late, because we conceived it to be an important war duty to aid the speeding up of production in this country by advocating lighting which will help every worker to do his best.

Frederick J. Pearson at the April meeting of the Chicago Section of the Illuminating Engineering Society briefly mentioned some commercial experiments in lighting which are full of interest both commercially and scientifically. That it has been demonstrated by a large mercantile establishment that illumination intensities considerably in excess of the intensities required for easy vision when applied to one department of a store showed increased sales traceable to no other cause than the increase in illumination is full of interest both to merchant and psychologist. It immediately brings up the question whether there is not something more than the mere improvement in visual acuity, however important that may be, to be considered in connection with increases of illumination intensity. The stimulating effect of sunshine and the depressing effect of cloudy weather are well known and in large organizations are directly reflected in the performance records of employees. If brighter lighting stimulates the customer to make purchases, may it not likewise in the office and factory stimulate the worker to more rapid and better work? In so far as it enables him to see better undoubtedly it will help, but beyond that there is an unexplored region of considerable promise, if we are to judge from Mr. Pearson's results supplemented by some well-known facts of human psychology. Just how far it may be worth while to go in the direction of brighter lighting to get this effect is, of course, as yet altogether uncertain, but when the over-all efficiency of a manufacturing establishment is the thing

most sought, rather than petty saving in one relatively small item such as artificial lighting, this is a point well worth studying and of immediate commercial importance in these times of forced production.

Standardizing Distribution Construction

IN SMALL plants no very systematic records of construction methods and material are generally to be found. A complete and systematized scheme of construction seems to be, and often is, somewhat burdensome, and there is a constant tendency to leave too much to loose memoranda or to the memory of the foreman. As the distribution system gets more extensive, lack of records leads sooner or later to an indefinite amount of annoyance. Construction departments will find H. E. Wulff's account of the standardized methods employed by the Commonwealth Edison Company a very useful guide in doing their work in an orderly and efficient manner. To establish a standard is in itself no easy matter, since every place and almost every job has its own individual character.

Perhaps the best scheme is to do the work gradually, settling down upon a few types as the dominant ones in ordinary practice and endeavoring as far as feasible to make others conform to them. If construction gangs are thoroughly saturated with the idea of doing work in a perfectly regular manner according to orderly standards, even if very simple ones, their work will be much facilitated and costs will run lower than they generally do. The system worked out for the Commonwealth Edison Company has, of course, to be elaborate by reason of the immense number of details with which it has to deal. That for the ordinary company is relatively simple, but the same general principles can be carried on throughout with admirable results. Only in a few cases will it be found necessary to adopt in its completeness a scheme based on extensive and diverse work. The plan described by Mr. Wulff seems to cover effectively about every case which is liable to arise even in the operation of a very large system. Of course, the details of the classification will differ from place to place; but the system of symbols and numbers reduced to terms of local necessities seems to be a very efficient one. Especially to be commended is the plan laid out for standardizing transformer installations, the effect of which is to obviate the necessity for troublesome and expensive changes when the size of transformers is increased to meet the burdens of added load.

Inspection and Care of Transformers

THE distribution transformer is the main stay of lighting and power service. It is likewise the element of distribution which on the whole requires the most careful watching. The paper in our current issue on the systematic inspection and care of the many transformers that come back from the lines for one reason or another is one in which central-station men should have particular interest. The most serious source of trouble with transformers is, of course, in the coils themselves; but there are subsidiary causes of trouble in the bushings, leads, oil and casings which

are often annoying. The first three of these are especially likely to be in evidence with the higher-voltage transformers. Bushings in such cases are rather large and run some considerable risk of breakage, particularly in handling the transformers. The least sign of break or looseness should be remedied by replacement at the earliest possible moment. There is constant danger of electrical leakage from a combination of dirt and oil, especially in the older type of bushings, and when repairs have to be executed the chance should be taken of replacing out-of-date forms with the later ones, which are likely to give less future trouble. To this end a good supply of spare bushings should be kept on hand so that there may be no temptation to adopt makeshifts which are very likely to prove unsatisfactory. In sealing in the new bushings particular care should be taken to see that no cracks permitting leakage are established by hasty replacements.

The transformer leads are likewise common sources of failure. They become soaked with oil, which in the case of rubber-covered leads brings serious damage to the insulation; leads are frequently broken in handling, or cut too short, and when the transformers are removed trouble is imminent. Of course, the main difficulty is with the primary leads, and constant watchfulness is required to see that the leads substituted for the old ones are adequate and are installed with particular care to avoid siphoning the oil, which stranded leads tend considerably to encourage. The oil itself cannot receive too close inspection; sooner or later it accumulates sludge and frequently absorbs moisture. It is a popular error that oil and water do not mix. They do, as every electrical man knows to his sorrow, and the utmost caution is necessary to see that the older oil has not absorbed water, and that the supply used to replace it has not been so stored as to expose it to the same risk. The higher the voltage of the transformer the more consideration must be given to this particular thing. Many a transformer has failed merely as the result of a leaky case. Constant inspection is the only road to safety. Of course, the coils themselves are always to be watched; sometimes a transformer coming in from the lines is clearly and evidently burned out beyond repair. Then, if small and old, it is probably cheaper to scrap it than do anything else with it. If only secondary coils chance to be involved and the transformer is a new one, it may sometimes be rewound at home. But the standard types can most frequently be returned for repair or exchange to the makers to the best advantage. In high-voltage transmission transformers, however, a supply of coils, kept carefully dry, is needed, inasmuch as the windings are usually of a somewhat special character and cannot be obtained without considerable delay.

The Performance of Polyphase Induction Motors

THE polyphase induction motor possesses the peculiar property that the electrical conditions which favor good performance at starting are opposite to those which favor good performance at full-speed running. In order to secure a powerful starting torque, with, say, rated-load current strength taken from the mains, the resistance of the secondary element should be relatively high; whereas, on the contrary, in order to secure good speed regulation and efficiency under normal running conditions, the resistance of the secondary element should be low. If, then, the secondary resistance is to remain unchanged, a compromise value may have to be effected, which limits good performance both during starting and during running. Advantage is sometimes taken, however, of the relatively low frequency of the secondary currents at full speed by making the secondary conductors in the form of straps, so as automatically to offer higher resistance, by edge effect, to the full alternating-current frequency encountered at starting.

The article by Justin Lebovici, beginning on page 866, discusses the relative advantages of different types of induction motors. In the case of squirrel-cage motors a strong and hardy mechanical construction is arrived at; but with no change made in the secondary resistance a compromise between starting and full-speed performance is ordinarily aimed at. If, however, the secondary is phase-wound and connected to external adjustable resistances, through strip rings and brushes, the performance can be made satisfactory during both starting and running, but the machine costs more.

An intermediate type of induction motor has long been used in which resistances carried around within the rotor secondary are short-circuited by means of a hand-operated lever when full speed is reached. The article points out the advantages which pertain to motors of this type when the secondary resistance control is made automatic by means of a centrifugal device. The starting resistances within the rotor are thus cut out of the secondary circuit as soon as the rotor attains an assigned fraction of synchronous speed.

Induction-motor designers very generally employ the phrase "torque expressed in synchronous watts." This expression is well understood, but is most unfortunate from a logical standpoint, since a torque cannot properly be expressed in watts, a torque being a couple of forces, whereas watts are power. Since, however, a torque multiplied by synchronous angular velocity develops watts, the self-contradiction would disappear if the phrase were changed to "torque expressed in watts per synchronous angular velocity."

THE current-limiting reactor is rapidly becoming an indispensable adjunct to electric service systems. In view of this fact the ELECTRICAL WORLD will tell in an early issue what considerations should be taken into account in installing it and how it should be maintained to secure the maximum effectiveness. Another article will dwell on the features of recent additions to the Northwest station of the Commonwealth Edison Company, which will shortly be equipped to generate 165,000 kw. with

The Coming Issues

six units. Some of the problems connected with the support of long-span conductors will be discussed in another article contributed to by several prominent Pacific Coast engineers. Factors which must be taken into consideration in selecting, installing and operating motor and control apparatus for industries which are found in nearly every section of the country will also be discussed. A precision method of measuring alternating currents will be explained.

Waste of Power at Niagara

Company Trying to Co-operate in Winning the War, but Continued Unwillingness of Congress to Act Means Insufficiency of Power for Growing Industrial Requirements

AT NIAGARA, the scene of the mighty cataract, there is a power famine. While water falls away over the cliffs great industries, most of which are busy on war work, suffer for lack of sufficient power to operate their plants at the full capacity for which they were designed.

The Niagara Falls Power Company, says Stacy C. Richmond, the president, "is endeavoring in every way to co-operate with the United States War Department to make Niagara power of the greatest possible service toward winning the war."

CONGRESS IS HELD TO BE TO BLAME

Yet in his annual report to stockholders Mr. Richmond is forced to explain that the insufficiency of power at Niagara to supply present requirements is due largely, if not wholly, to the continued unwillingness of Congress, since the question of federal control of Niagara diversion was first raised in 1906, to enact permanent provision for the subject and to fix the status and the rights of the companies which had constructed expensive plants pursuant to authority of New York State and had been lawfully operating for many years before their rights were first called into question.

During this time the Niagara company has stood ready upon any reasonable permanent settlement of its rights at least to complete its original undertaking, says Mr. Richmond. This would have substantially doubled the present output of the American plant with little, if any, diversion of water above the amount now in use by it under the existing temporary permit.

The permit for the additional diversion and the authority of the Secretary of War to grant like permits will expire with June 30, 1918, unless meantime Congress shall take further action, as the resolutions of Congress expressly provide that a diversion of any water from the Niagara River after that date in excess of the limitations of the expired Burton law shall be a misdemeanor subject to punishment by heavy penalties.

President Richmond refers to the Secretary of War's order of Dec. 28, 1917, under which the President of the United States requisitioned until further notice the total quantity and output of electric power produced or capable of being produced by the company as well as that delivered to it in the United States from Canada. The order provides that it must be given precedence over any and all orders theretofore placed with the company. Its effect deprives, therefore, some customers of power heretofore delivered them under contracts of long standing and for long terms, increasing the supply to others whose products the federal administration considers more essential to the successful conduct of the war.

Increases in the demands for the indispensable products of Niagara power have been caused by the war. "The federal authorities now have recognized

the fact," comments Mr. Richmond, "that the amount of Niagara power available is wholly inadequate for use in the production of sufficient quantities of the articles required to supply the nation's needs and at the same time to supply ordinary business requirements."

Operations in Canada are affected by the attitude of the authorities there. The tenth unit in the plant of the associated Canadian Niagara Power Company was completed and placed in commercial service in January, 1917. The generating installation of that company is now somewhat in excess of 100,000 hp. As showing that more energy could be generated in this plant the company says that its present head works, power house and tunnel are adequate for the installation of another large generating unit.

"The Ontario government, however," says Mr. Richmond, "now claims that the present rights of the Canadian company are limited to the production of 100,000 hp. In this view the company finds itself unable to concur."

Some changes in the Niagara situation are promised by the proposed consolidation of the Niagara Falls Power Company, the Hydraulic Power Company and the subsidiary of the latter company, the Cliff Electrical Distributing Company. This consolidation is authorized in a bill which has been passed by the New York Legislature. Under its terms the rearrangement of securities is subject to the approval of the Public Service Commission.

FIFTEEN MILLION DOLLARS FOR NEW PLANT

It is estimated that this consolidation will be followed by the expenditure of \$15,000,000 for new plant and equipment and that with co-ordination of the properties there will be a total resultant increase in output of 170,000 hp. over the energy that is now generated by the existing properties. Unification of the properties was favored by a representative of the War Department who testified at the hearings before a committee of the Legislature. It is, therefore, as a war measure that the matter has been subjected to investigation and urged before the Legislature with such effect that that body took action.

It is calculated by the Niagara Falls Power Company that for at least the period of the war double the present output of all existing plants could be sold in the districts reached by the power supply.

No one will minimize the present urgent demand for power for industries vitally necessary to the war. The industries at Niagara and in the nearby cities reached through transmission lines require power in peace or war time. Grave need of conservation of coal supplies and of the time of labor and the service of transportation point to the logical conclusion that unessential waste should stop. The scenic beauty of Niagara can be preserved while at the same time more water is diverted and conservation made a fact.

Performance of Polyphase Induction Motors

Choice Should Depend on Nature and Magnitude of Load, Allowable Starting and Running Current, Frequency of Starting and Efficiency of Operation

BY JUSTIN LEBOVICI

Designing Engineer, Triumph Electric Company

TO DETERMINE what type of induction motor is best suited to a particular application it is, of course, necessary to know the nature and magnitude of the load, the allowable starting and running current, the frequency of starting and the relative characteristics of the different types of motors. In what follows the writer will therefore compare some of the commonly used types of polyphase induction motors, taking into consideration different methods of starting them.

SQUIRREL-CAGE MOTORS

I. *Resistance in Series with Primary Winding.*—The torque T in synchronous watts is given by

$$T = M_s I_s^2 R_s / S \quad (1)$$

where M_s represents the number of phases in the secondary winding, I_s is the secondary current per phase at full load, R_s is the resistance per phase, N is the ratio of starting current to full load current, and S is the slip. In starting $S = 1$, and assuming $I_{\text{start}} = NI_s$ and substituting in (1) the starting torque

$$T_1 = M_s N^2 I_s^2 R_s \quad (2)$$

Combining (1) and (2),

$$T_1 = SN^2 T. \quad (3)$$

Allowing a full-load slip of 4 per cent and a starting current equal to three times full-load current, $T_1 = 0.04 \times 3^2 \times T = 0.36T$, or about one-third normal torque will be developed with three times full-load current taken from the line.

When started with resistance in series with the primary winding, a squirrel-cage motor having 4 per cent slip at full load will take at least five times full-load current from the line in order to develop full-load torque. Evidently this method of starting is inefficient when a torque of from two to three times normal value is needed, but it does not affect the generator regulation so severely as an auto-transformer. Since the resistance is cut out gradually there is no rush of current such as occurs in motors started by means of an auto-transformer when the handle is thrown over from the starting position to the running position.

II. *Auto-Transformers.*—When an auto-transformer is used in starting squirrel-cage motors it reduces the voltage at the motor terminals and the value of the locked current in the same proportion. The primary winding of the auto-transformer will draw less than the motor current from the line, the amount being inversely proportional to the reduction in voltage.

For a normal 50 hp. squirrel-cage motor with a locked current of six or seven times normal, three times full-load line current will be obtained on approximately the 65 per cent tap. The motor current is greater than the line current by the ratio of transformation ($3/0.65 = 4.6$ times normal current) and for a full-load slip of 4 per cent the starting torque $T_1 = 0.04 \times 4.6^2 \times T = 0.85T$. This exceeds double that in case I for the same

line current, so this method is not advisable when two to three times full-load starting torque is needed and the line current limit is three times full-load current (Fig. 1).

For the sizes of motors under consideration (5 hp. to 75 hp.) the scheme of connections shown in Fig. 2 is in common use. The auto-transformer is Y-connected, the motor being a normal star-connected or delta-connected motor. There is no appreciable drop in phase I between the terminal A and the line L_1 , but there are drops in the auto-transformers between the line L_1 and the terminal B and between the line L_2 and the terminal C. The result is that the voltages AB, BC and AC applied to the motor terminals are unbalanced, which results in a reduction of the starting torque of the motor per ampere taken from the line as shown in Fig. 3.

III. *Star-Delta Connection.*—A delta connection of the primary winding for the running condition and star during the starting period is equivalent to a 58 per cent tap on the auto-transformer and reduces the starting torque and line current to about one-third of full-voltage values. The purpose of the starting device

FIG. 1—STARTING CHARACTERISTICS OF SQUIRREL-CAGE MOTOR ON 66 PER CENT TRANSFORMER TAP.

Current and torque in per cent of full-load values based on the assumption that a tap is used on the auto-transformer limiting the line current to three times normal. The lever is thrown over to the running position at 80 per cent of full-load speed, which results in a rush of current just before the motor reaches full load speed of four to five times normal current. This does not take into account the drop in voltage in the auto-transformer itself, which may easily reach 15 per cent of the voltage applied at the motor terminals, owing to the intermittent service for which this apparatus is designed.

is to limit the line current to such a value as not to cause fluctuations in voltage which might affect other apparatus on the same circuit.

General Remarks.—The undesirable fluctuation in voltage when a squirrel cage motor is started may be due either to the excessive current taken from the line or its low power factor affecting the regulation of the alternator and the transformer. An auto starter introduces a considerable wattless component of current, owing to the leakage of the auto-transformer and to the high magnetizing current made necessary by the intermittent duty for which auto-transformers are built. Auto-transformers require the attention of a skilled operator to prevent their burning out owing either to maintaining the lever in the starting position

too long or to line disturbances caused by changing over too quickly. If line disturbances are to be avoided, it is impossible to start induction motors by any of the above methods when a starting torque of one and one-half to three times full-load torque is required. To pre-

FIGS. 2, 3, 4 AND 5—USE OF Y-CONNECTED AUTO-TRANSFORMER FOR STARTING AND UNBALANCING OF VOLTAGES PRODUCED; SELF-STARTING MOTOR CONNECTIONS IN STARTING AND RUNNING CONDITIONS

The rotor shown in Figs. 4 and 5 is connected in a single star winding, each phase being split in two parts of unequal resistance. Phase I is divided at A and A_1 ; phase II into two parts, B and B_1 ; phase III into parts C and C_1 . Variable resistances are obtained by winding A , B and C with a different-size wire of unequal number of turns and wound with a different resistance material from A_1 , B_1 and C_1 . During the starting period the groups A and A_1 , B and B_1 , C and C_1 are connected in series as shown in Fig. 4. From the junction point between windings A and A_1 , B and B_1 , C and C_1 , leads X_1 , Y_1 , Z_1 are brought to one side of the switches X , Y and Z , the other sides of the switches X , Y and Z being connected to a short-circuiting ring. While the motor accelerates from zero speed to about 80 per cent of full-load speed, the switches X , Y and Z are open, but at the latter speed they are automatically closed.

vent the rotors of the squirrel-cage motors sticking at a subsynchronous speed when starting, it is necessary to make the resistance of the end rings sufficient to give the motor a torque above the friction torque. The starting torque can be improved by using deep slots and bars in the rotor, as this construction will increase the effective resistance at or near stand-still. On the other hand, if the bars are too deep the secondary slot leakage is increased, resulting in a low power-factor motor. Hence advantage can be taken of the deep rotor bar only to a limited extent if the normal load characteristics of the machine are to be maintained.

PHASE-WOUND ROTOR

Resistance in the Secondary.—From equation (2) it can be seen that increasing the secondary resistance R_2 raises the starting torque of the motor. As soon as the pull-out torque is reached, however, a further increase in resistance will reduce the starting torque, because I_2 drops faster than R_2 increases. Starting wound-rotor induction motors with resistance in the secondary is efficient and desirable as it is possible with a skilled operator to keep the current to a minimum during the entire starting period. The efficiency of the motor is not affected by the high starting resistance because it is cut out of circuit when the machine is operating under full-load conditions.

Since this method of starting necessitates the use of a phase-wound rotor, slip rings, brush holders and

brushes, however, it is more expensive than using a squirrel-cage motor with auto-starter control in the primary. On the other hand, the wound-rotor controller is more durable, having only to short-circuit the resistance steps instead of breaking the circuit. There is less burning out of controller fingers, and the starting operation is quieter, but if the controller handle is moved too quickly over the contacts sudden rushes of current are liable to occur. In order to minimize the cost of the complete outfit, one single resistance step can be used in each phase and assembled on the rotor, thus eliminating slip rings and brush rigging.

For most industrial applications, such as the operation of motor-generator sets, pumps, blowers, line-shafting, cotton mills, wood-working machinery, etc., the internal secondary resistance must not be too high because the efficiency of the machine is directly affected by the copper losses in the secondary; and a slip as high as 6 to 8 per cent is considered prohibitive in such motors.

STARTERLESS MOTORS

Several types of starterless motors have been developed which will be briefly described before comparing them with the motors mentioned. For instance, Boucherot employs two separate fields, one of which is capable of rotation (either mechanically or by means of an induction regulator), the fields opposing each other during the starting period, one being gradually rotated

until it coincides with the other in rotation. Another type of motor which is extensively used involves a high-resistance squirrel-cage or phase winding for starting and a low-resistance polyphase rotor winding which is open during the starting period but closed when the

motor is nearing full speed. Another scheme proposed by Boucherot is to use two squirrel-cage windings, one of high resistance and low reactance active during the starting period, and one of low resistance and high reactance (at the high rotor frequency which occurs during the starting period), to assist the first squirrel cage after the motor has attained full speed. The use of

FIG. 6—STARTING CHARACTERISTICS OF SELF-STARTING MOTOR

Motor operates on principle shown in Figs. 4 and 5. The curves are obtained from a 50-hp., 1200-r.p.m., 60-cycle motor and are counterparts of those shown in Fig. 1 obtained from a squirrel-cage motor of the same rating.

deep narrow slots has been mentioned to increase the skin effect during starting and thus increase the starting torque.

To prevent the crawling of squirrel-cage motors at subsynchronous speeds Punga has proposed using a combination of a phase winding and a squirrel-cage winding in which the coils are embedded in slots and connected to an end ring. The pitch is so chosen that one side of one coil lies under a tooth and the other side of the coil lies under a slot opening. The pitch of the coil is such that the seventh harmonic is avoided. J. Fisher-Hinnen had proposed tubes having high specific resistance material as rotor bars, these being connected to end rings in the usual manner. Rods of low-resistance material fitting into these tubes are gradually inserted in the tubes as the motor is speeding up. Use is also made of a three-phase rotor of normal construction equipped with carbon-disk resistors in each phase. As the rotor speeds up centrifugal weights increase the pressure between the carbon disks, thus decreasing the rotor resistance.

A self-starting motor which works on the principle shown in Figs. 4 and 5 has just recently been developed. With this type the initial investment can be minimized and in many instances greater efficiency can be obtained.

FIGS. 7, 8 AND 9—SELF-STARTING ARRANGEMENT OF ROTOR WINDING FOR LARGE MOTORS

The starting torque (Fig. 6) can be made any value up to the pull-out torque of the motor by properly selecting the resistance of A , A_1 , B , B_1 , C and C_1 , and the slip under normal operating conditions can be made relatively low. The practicability of operating the motor by remote control and where it will not receive expert attention is another feature.

By properly selecting the pitch of the rotor winding the tendency to creep or stick at a subsynchronous speed is eliminated. If for any reason the supply voltage fails, the motor stops and the rotor connections automatically return to the starting connections and no damage to the motor due to the supply voltage results. It is this feature which makes this type of motor applicable for remote control.

With the arrangement shown all of the rotor windings are active during the starting period and also while running, but not to the same extent. The completed rotor winding is not different from an ordinary phase-wound rotor, and any difficulties due to assembling the revolving resistance units are eliminated. The centrifugal device for changing the rotor connections from the starting to the running condition is simple and rugged, there being only three rotating switches to be closed. The switches X , Y and Z never break a circuit, thus eliminating burning at the contacts, a most troublesome feature of switches operating in air. In larger machines the windings A_1 , B_1 and C_1 of Figs. 4 and 5 are split and short-circuited successively. The performance of a 75-hp. motor having the rotor winding divided as shown in Figs. 7, 8 and 9 is shown in Fig. 10. The torque is equal to $M_2 N_2^2 I_2^2 (R_2' + R_2'')$, where

FIG. 10—PERFORMANCE OF MOTOR STARTED BY PRINCIPLE SHOWN IN FIGS. 7, 8 AND 9

R_2' and R_2'' are the resistances of A , B , C and A_1 , B_1 , C_1 respectively.

COMPARISON OF ENERGY CONSUMPTION AND HEATING DURING ACCELERATION

Data on the relative energy consumption and heating of squirrel-cage induction motors and the self-starting motor just described are given in the accompanying table. To permit comparison it is assumed that the entire weight to be accelerated is concentrated in a flywheel on the rotor shaft, a 60-in. (152-cm.), 750-lb. (340-kg.) flywheel being selected for this example. Three-phase, 60-cycle, 50-hp., 1200-r.p.m. motors having the characteristics shown in Figs. 1 and 6 are considered. In both cases it is assumed that the starting current is limited to three times the full-load current. This puts a premium on the inefficient motor, but in the case under consideration the full-load efficiency and current are approximately the same for both motors, although the distribution of losses is different.

Owing to the fact that the cost of the auto-transformer is eliminated with the starterless motors, it is possible for the same expense to design this machine with somewhat more liberal dimensions than the squirrel-cage motor, use higher rotor resistance, lower primary resistance and obtain lower core losses, thus permitting the same over-all efficiency but improved starting characteristics.

From the data it can be seen that the squirrel-cage motor plus a starter consumes 2.73 times as much energy as the starterless motor to accelerate the same load to full speed. A slip-ring motor, if properly handled, will effect a still greater saving, but the starterless motor is cheaper in first cost and simpler to operate and maintain.

A squirrel-cage motor having the bars and end rings correctly proportioned would give nearly the same results during the starting period, but the full-load slip would be high, the full-load efficiency low and the heating of the machine under continuous operation prohibitive. Such motors are limited in their application to elevator and allied intermittent use.

Government Wages to Electrical Men

Analysis and Classification of Compensation Provided for Next Fiscal Year for More Than 1200 Men Engaged in Different Electrical Occupations That Contribute to the Nation's War Program

IN THE estimates of appropriations required by the several United States government offices and executive departments for the fiscal year to end June 30, 1919, are found the salaries and wages for electrical men of all kinds.

Compensation is not at all regular. Some salaries are on an annual basis, some are monthly, some per diem, and still others on an hourly rate. The list runs all the way from a salary of \$4,800 per annum for an electrical engineer to \$1.04 per diem for electricians.

Provision is made for a total of 860 electricians, wiremen and helpers. Chief electricians are to receive as high as \$2,280 per annum and as low as \$1,400 per annum. Electricians are to receive on the annual basis as high as \$1,800 and as low as \$360; on the monthly basis from \$60 to \$150, and on the per diem basis from \$1.04 to \$6. Wiremen are to receive annual payment as high as \$1,950 and as low as \$900; on the per diem basis from \$2.52 to \$4.80, and 74 cents hourly. Helpers in a few cases are provided for at an annual or monthly rate. They are generally on the per diem basis, which ranges in their case from \$2 to \$4. The hourly basis rate is 42 cents.

Electrical engineering talent is generally provided for on an annual salary basis. These salaries range from \$1,200 to \$4,800. Electrical experts are to receive as high as \$12 per diem and as low as \$4. Electrical draftsmen will average \$5.35 per diem, ranging from \$3.76 to \$12.48. In the electrical engineering class positions are made for 193 men.

To take care of the various kinds of plant and line work provision is made for 223 men. Generally speaking, these places call for annual or monthly salaries.

All told, the estimates call for the employment of 1276 electrical men. The detailed figures on the number to be employed, the different groups, and the average compensation to be paid, together with the upper and lower limits, are to be found in the accompanying tables:

Number of Electricians and Rate	High	Low
5 chiefs, average \$1,776 per annum.....	\$2,280	\$1,400
263, average \$1,122 per annum.....	1,800	780
20 from \$360 to \$1,000 per annum.

2 stationary engineers at \$225 per month.		
1 electrical recorder at \$200 per month.		
3 wiremen operators, at \$165 per month.		
21 switchboard operators, average \$155.28 per month.....	187.50	140
3 substation operators, at \$1,200 per annum.		
2 telephone operators, average \$97.75 per month.	103.50	92
2 operators, from \$75 to \$90 per month.		
3 operators, at \$90 per month.		
25 chauffeur-operators, at \$75 to \$120 per month.		
14 dynamo tenders, average \$995 per annum.....	1,080	875
7 dynamo tenders, at \$4 per diem.		
8 skilled laborers, at \$2.50 per diem.		
6 wheel tenders, at \$2.50 per diem.		
9 battery repairmen, average \$151.40 per month..	162.50	137.50
1 instrument repairman, average \$165 per month.		
7 signal maintenances, at \$150 per month.		
1 engine man and erector, at \$900 per annum.		
3 switchboard men, at \$360 per annum.		

Standardization of Overhead Construction

Considerations That Were Taken Into Account in the Determination of the Types of Line Construction Now Used—A Numerical System of Specifying That Has Been Found of Assistance in the Reduction of Costs

BY H. E. WULFING

Commonwealth Edison Company, Chicago

STANDARDIZATION of construction in any line of work results in decided advantages at any time, but especially so under present conditions. There are a few advantages peculiar to overhead line construction which will bear emphasis. First, standardization eliminates the carrying in stock of special material to satisfy the ideas of the several foremen or

for the Commonwealth Edison Company of Chicago are given in the following paragraphs.

In this program of standardization, which extended over a period of two years, several requirements were considered. They were safety, simplicity, neatness in appearance, uniformity, practicability, fitness for a progressive construction program, and cost.

HOW CABLE POLE CONSTRUCTION WAS STANDARDIZED

In order to give a concrete illustration of the manner in which some of these requirements have been met, the steps followed in standardizing a cable pole will be explained. When the standardization of cable poles was considered it was found that there were several types of construction in existence. This condition existed because men in charge of work in various districts had followed their own ideas and worked independently. The best type was selected, and the question of safety was first considered. This pole contained six alley arms and three buck-arms and was designed to carry twelve potheads. It was found that the safety of the pole could be improved by adding another arm, on which the linemen could stand while inspecting lightning arresters. This further loaded the already overburdened and unsightly pole. While the question of safety had thus been taken care of, simplicity of construction and neatness in appearance had been neglected. In order to attain this it was necessary to reduce the number of arms on the pole.

It was found that the number of cases in which it was necessary to install twelve potheads on a cable pole were few. Therefore it was decided to design the cable pole for eight potheads, taking care of the cases in which twelve potheads were needed by setting another cable pole. This permitted the reduction of the

FIG. 1—TYPICAL METHOD OF INDICATING WORK ON JOB ORDER

superintendents engaged in the work. Next, it reduces the amount of material which has to be carried in stock by reducing the number of kinds of units needed. Third, it permits of accurately determining in advance the correct amount of material needed on each job, since the material for each standard is definitely known and the material for a job will be equal to the sum of the material for the standards in connection with the job. In addition, it increases the efficiency of the gang, owing to the fact that the repeated performance of a job in a definite way increases the speed with which it is done. Again, it establishes uniform construction throughout the system. Sixth, it permits a comparison of the relative value of the gangs, as each gang does the same units of work in the same manner. And last, but not least, it reduces the cost of doing the work.

The establishment of standards for overhead construction is not so simple as in most other work, however. No two jobs are alike and, while the elements of a job may be similar, the conditions under which it will be done are different in each case. However, if overhead line work is to be made uniform, simple, neat in appearance and easy to designate, there must be standards. The method of establishing such standards

FIG. 2—STANDARD CABLE-POLE CONSTRUCTION ADOPTED

number of buck-arms by one. The standing arm, which was originally installed for safety in inspecting lightning arresters, was then eliminated by installing the non-inspecting type of lightning arresters. Further consideration resulted in the elimination of services from the cable pole, and a standard was finally adopted having only three buck-arms and four line-arms as

against the old type, which had four buck-arms and seven line-arms. The new standard (Fig. 2) is safer, simpler, neater in appearance, more practicable and costs less than any construction which was formerly used.

A good illustration of progressive construction is given by the present type of standards for transformer

FIG. 3—TYPICAL CONSTRUCTION FOR SMALL TRANSFORMER INSTALLATIONS

installations. An investigation of the different types of construction brought out the fact that, as was found with the cable poles, there were many methods of installing transformers. It was also found that as the load on a transformer increases, and it is necessary to increase its size and therefore increase the strength of the equipment for holding the transformer, it would be practically necessary in most cases to dismantle the previous construction and rebuild the transformer pole. Safety and appearance were already fairly well taken into consideration, so that the main question was one of progressive construction.

In the plan which was finally adopted the transformers are divided into groups with a type of installation for each group. The installations are so planned that when it is necessary to increase the size of a transformer of one group to the next larger it is merely necessary to add another arm without disturbing the existing equipment other than the transformer itself. Incidentally, simplicity and neatness in appearance were attained by providing heavier arms to sup-

FIG. 4—AMPLE SPACE IS PROVIDED FOR LARGE TRANSFORMER BY BRACING USED, WHILE EXTRA STRENGTH IS AFFORDED BY DOUBLE BUCK-ARM HOLDING TRANSFORMER

port the transformers rather than by doubling the smaller sizes of arms (see Figs. 3 and 4). A change from the construction shown in Fig. 3 to that in Fig. 4 can be made by merely adding a short buck-arm for additional strength without any change in wiring.

Once having established a standard, there are two things to be accomplished in order to put this standard

into effect: First, to familiarize the man on the job with the construction standard; second, to devise a scheme for specifying the standard on the job print. In order to keep the man on the job in touch with standard construction, each gang foreman is supplied with a book of standards known as the "Overhead Construction Specifications." This book is pocket-size and contains a description of the methods of construction and prints of all the standards commonly used, together with a list of material for each type of construction. The foreman is thus furnished with authoritative information on whatever work he has in hand.

On account of the large number of standards of overhead construction, it was evident that some system of symbols must be adopted in order that the standards

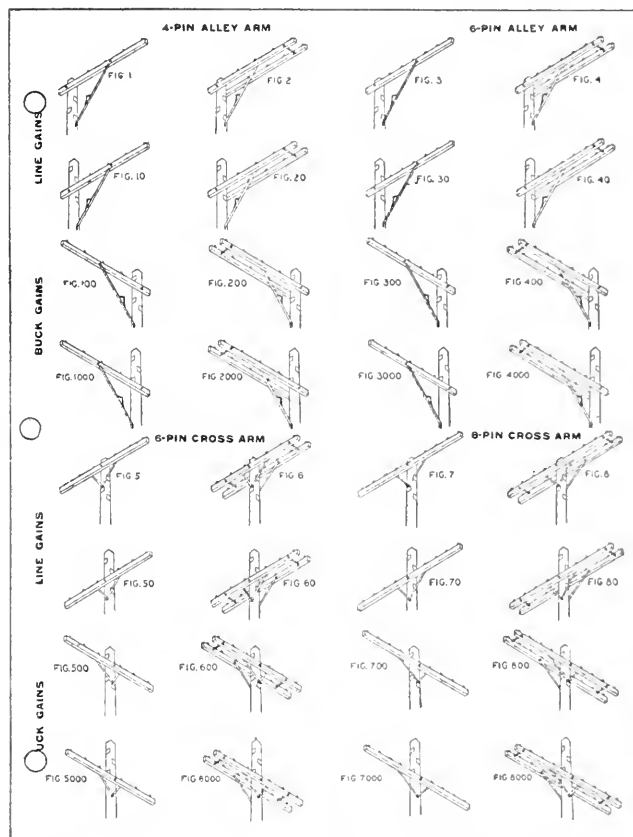

FIG. 5—POLE-TOP CONSTRUCTION CLASSIFIED BY POSITION OF CROSS-ARMS ON POLE

might be classified and to permit ease of reference and specification on the job print. For this purpose the standards are divided into groups according to types—for example, cable poles in one group, transformer poles in another, line poles in another, etc. To each group is given a series of numbers sufficient to take care of the present standards and to allow for future standards that may be established. These symbols or numbers for designating the different types of standard construction permit ready reference to the various groups and allow the use of simple specifications on the prints and job sheets. The foreman and men soon become familiar with the symbols and refer to the types of construction by symbol numbers instead of by description.

In attempting to establish standards for the overhead work, it was found that they naturally divide themselves into two groups—one line poles, the other special

poles. The number of special poles is limited, and it was a simple matter to assign symbol numbers to them; but when it came to the question of assigning symbol numbers to line poles it was found that there were so many possible combinations of arms on a pole that the making of a sketch and assigning symbols to each combination was out of the question. It was therefore necessary to establish some scheme that would permit the definite designation of the arming of a line pole without the necessity of assigning to each group of arms a separate sketch and symbol.

Study on a scheme of this kind resulted in the application of a decimal system (Fig. 5) for designating the arming of line poles. For instance, referring to the group of small figures in this illustration, Fig. 1 is a four-pin alley arm on the top line gain. When placed on the second line gain it is called Fig. 10; on the first buck gain, Fig. 100, and on the second buck gain, Fig. 1000. The arm doubled is designated by the next even number. In other words, the number designates the arm, and the units, tens, hundreds or thousands in a figure designate the position of the arm on the pole. For example, Fig. 30 represents a six-pin alley arm on the second line gain—the figure 3 identifying it as a six-pin alley arm, and its being in the tenth position identifying its location on the second line gain.

The specifying of the arming of a line pole is thus reduced to a symbol consisting of no more than four digits, and any combination of four arms, either single or double, on any of the four positions can be specified by means of the decimal system shown. To illustrate further: Fig. 632 designates the arming of an ordinary line pole from which a service is taken and specifies that a double four-pin alley arm is installed on the top line gain, a single six-pin alley arm on the second line gain and a double six-pin buck-arm on the first buck gain. The simplicity of the designating of the arming of line poles should be evident.

STATUS OF POWER SUPPLY IN THE JAPANESE EMPIRE

Installed Capacity of Electrical Plants Is More Than 500,000 Kw., with 460,000 Kw. Additional Under Construction at Close of 1917

According to the official publication of the Department of Communications, the status of electrical industry in Japan at the close of 1917 was as follows: Central stations, 582; electric railways, 40; central stations and railways, 48, a total of 670, or an increase over 1916 of 42.

Total capital for central stations, \$182,347,955; for railways, \$21,423,985; for railway and central stations, \$159,443,346, making a total of \$363,215,285, an increase over 1916 of \$31,038,335.

The generating capacity in kilowatts at the close of 1917 for the different classes was as follows:

	Central Stations	Railways	Central Stations and Railways	Total	Increase Over 1916
Completed:					
Water	327,458	180	73,799	401,439	26,553
Coal	49,251	1,175	64,936	115,362	5,667
Under construction:					
Water	278,911	850	17,307	297,068	44,738
Coal	118,419	3,450	41,400	163,269	137,674
Total:					
Water	606,369	1,030	91,106	698,505	71,291
Coal	167,670	4,625	106,336	298,631	132,007
Both	774,039	5,655	197,442	977,136	203,298

Safest on Earth—Liberty Bonds

Book Review

THE LIGHTING ART. By M. Luckiesh. New York: McGraw-Hill Book Company, Inc. 230 pages, 43 illustrations. Price, \$2.50 net.

This latest of Mr. Luckiesh's admirable little books on light and color deals particularly with the artistic side of the subject in its various forms of application. The engineering technique of lighting has been many times dealt with in other specialized books, but, since Mrs. Gordon's "Decorative Electricity" many years ago, this is the first which has been devoted chiefly to the artistic finesse of artificial lighting. It therefore forms an admirable supplement to the literature of illumination. Particular attention should be directed to Mr. Luckiesh's consideration of artificial daylight and other special color modifications of illuminants. He is, perhaps, a little optimistic regarding artificial daylight and its applications, a most interesting development which has not yet proved especially fruitful. There is a subtle psychological situation which lies back of simulated daylight. To the ordinary eye all varieties of so-called artificial daylight look blue if anywhere nearly fully developed toward their ideal. The north sky is, of course, notorious for its large proportion of blue light, but this tone is strongly modified in interiors, so that if an artificial illuminant matches real north-sky light it still appears, if at all concentrated, strongly blue to the eye. None of the artificial daylights as yet produced is entirely free from objection, but they can be and are made to produce all degrees of approximations to the various phases of natural light. It is not so much the amount of variation from natural light that is important as it is the kind, and Mr. Luckiesh points out that certain devices producing an apparently good simulation are still bad on account of their weakness in certain colors. A given tint can be very closely matched by lights varying enormously in spectral composition. If the variation is in the usual direction suggested by a comparison between north sky and sunset, the eye, accustomed to just this particular kind of variation in its daily life, takes relatively little cognizance of it.

Another modification that enters into the subject and is briefly discussed by Dr. Luckiesh is the toning of relatively white electric lights to the warmer and to many eyes more pleasant hue produced by candle flame or oil lamp. The interesting point about this special problem is that the illumination thus toned can be obtained at a very much higher efficiency than that actually obtained for a similar color in using the old carbon lamps. This fact depends on the nature of the color filtering, which has proved to be a very difficult task, particularly since the most efficient color screens are of dyes which have been found to be somewhat fugitive. Mr. Luckiesh's volume should prove interesting to the general reader and particularly valuable to architect and decorator.

Buy Bonds, Still More Bonds

Condition of Electric Utilities in the War

Economic Factors Are Menacing, but They Are Balanced to a Certain Extent by Position of Companies as "Essential" Industries and Assurance of Great Demands for Power

WAYS of meeting the unprecedented conditions under which public utilities labor are discussed in reports to stockholders. Many details of special interest to the companies are presented from experience and they show that great care and wise forethought are needed to guide the properties through the troublesome problems of the present year. While readjustments of rates have been made in many communities, these changes alone have not removed all difficulties. Even where these increases have been approved by the state regulating commissions, they are not always adequate. The paramount issues of insufficient generating capacity to meet war demands, of cost as well as scarcity of materials, of uncertainty as to revenues and of depletion of forces by the national military exigency remain menacing. The shifting conditions which these influences promise for the future look serious, but they are certainly balanced to some extent by the fact that the utilities are in no doubt as to their rank as "essential" industries. Whatever else happens, the great electrical generating and distributing systems are assured that their output is one of the first products required for public service and winning the war.

PUBLIC SERVICE CORPORATION

Reviewing the 1917 operations, President Thomas N. McCarter of the Public Service Corporation of New Jersey said:

"The enormous increase in the cost and the shortage of labor; the vast increase in the cost of every commodity used in the operation of these properties, and the difficulty of obtaining materials all combined to create an unprecedented situation which is reflected in smaller depreciation charges and net earnings. The fuel bill alone of the three operating companies was approximately \$2,500,000 in excess of what it would have been for the same amount at 1916 prices."

The amount spent in maintenance, however, says Mr. McCarter, "largely exceeded that spent in previous years, owing to increased cost of labor and materials, and the properties have been well maintained."

Reference is made to the application for rate increases. A new electric schedule was authorized recently by the New Jersey commission.

The services of 833 trained men were lost to the operating companies, that number of employees having joined the army and navy. "While their loss is felt, this manifestation of loyalty to country is a source of gratification," Mr. McCarter adds.

In addition to serious difficulty in securing coal, the subsidiary Public Service Electric Company was materially handicapped "by the failure of manufacturing contractors, owing to war conditions, to deliver apparatus and supplies as promised." Nevertheless, much new construction was completed or begun.

"The policy of furnishing power in large amounts to customers at transmission voltage was continued, and

the tremendous demands made upon the company for war purposes necessitated a number of important installations of this character," writes Mr. McCarter. "It may be interesting to note that it is estimated that 67 per cent of the company's connected power load is being utilized indirectly in war business."

The net charge for capital expenditures by the Electric Company in the year was \$4,880,463.

NORTH AMERICAN COMPANY

President James D. Mortimer of the North American Company says that the process of procuring adjustments to compensate for increased costs of labor, fuel, supplies, taxes and money is very slow.

He declares that "public utilities are confronted with that same psychological inertia which has for years confronted the steam railroad carriers and brought about the congestion of facilities which reached its climax during the winter."

Mr. Mortimer expresses the hope that it will prove fortunate in the long run that the regulating commissions having jurisdiction over the utilities in the states in which the subsidiary utilities operate have not hesitated to assume jurisdiction over applications for increased rates.

Concerning financing and new construction, Mr. Mortimer writes:

"Immediately after the decision which resulted in the United States joining in the world war all the subsidiary companies put into effect changes by which their plans for expansion of plant and facilities were greatly contracted. Only that construction work was continued which was necessary to avoid losses or to carry out contracts incurred in prior months. Permanent financing of much of their capital expenditures has been impossible except at interest rates higher than the returns yielded by the business during even normal times. Depreciation reserves accrued during the year have been invested in additional plant and facilities and in materials and supplies. A very restricted construction program during the year 1918 and subsequent years as long as the war continues will leave reserve accounts available for the gradual payment of the indebtedness incurred during the year just closed."

Coal price fixing, says Mr. Mortimer, "has granted only partial relief. Operating expenses have been raised to a high plane from which complete relief is not yet in sight. Unit operating revenues have as a rule continued to decline, and the margin between revenues and costs has been contracted from both directions."

A temporary increase in electric rates of the Milwaukee Electric Railway & Light Company has been authorized by the Wisconsin Railroad Commission.

In discussing the affairs of the Missouri subsidiaries Mr. Mortimer mentions the acquisition by the Union Electric Light & Power Company of St. Louis of 3200 acres of coal lands. The property is near Duquoin, Ill.,

75 miles from St. Louis. The amount of workable coal is estimated at 36,000,000 tons, and the development of production is planned during 1918.

Referring to the successful policy adopted by the Union company of selling preferred stock to customers, Mr. Mortimer says that up to Dec. 31, 1917, a total of \$1,903,300 was subscribed.

As indicative of capital expenditures in 1917 the reports of some of the principal North American Company subsidiaries may be given. Expenditures of the Milwaukee Railway & Light Company, for additions, extensions and betterments, other than purchase of the Commonwealth Power Company system, amounted to \$2,328,405. Milwaukee Light, Heat & Traction Company expenditures were \$1,068,292, and those of the Wisconsin Gas & Electric Company were \$920,128. For the Union Electric Light & Power Company of St. Louis the total, excluding purchase of the Electric Company of Missouri, was \$3,537,012, but because of the removal from service of property valued at \$829,208 the net amount was \$2,707,804.

CITIES SERVICE COMPANY

The radical change in operations of the Cities Service Company is pointed out by President Henry L. Doherty in a statement showing the sources of gross revenues. In 1915 public utilities furnished 95 per cent of the \$4,479,800 total and oil operations 5 per cent. In 1916 public utilities contributed 55 per cent of the \$10,110,343 total and oil 45 per cent. In 1917 the aggregate amount was \$19,252,493, of which public utilities furnished 24.6 per cent and oil 75.4 per cent.

Speaking of fuel and labor costs and the cost and difficulty of delivery of supplies, Mr. Doherty said:

"Government restrictions and regulations regarding decorative and sign lighting and the development of the federal policy of safeguarding and extending service to essential industries by the curtailment of supply to non-essential users have introduced additional problems into an already difficult situation."

It became apparent, Mr. Doherty continues, that "service, earnings and investments could be protected only by increasing rates." Nearly every subsidiary was called upon to make adjustments. While this work was complicated by variations in rate-making authority in different states, consent was obtained during the year to adjust power and industrial rate schedules for practically every property.

After speaking of the new plant construction at Toledo, Mansfield, Ohio; Joplin, Mo., and Warren, Ohio, Mr. Doherty says: "Extensions to meet large industrial war requirements are under consideration. Progress on these, however, will be affected by plans for financing such requirements."

More than 750 employees entered government service, and President Doherty remarks that "it should be a source of patriotic satisfaction to all stockholders that the business of the subsidiaries is of essential usefulness in the prosecution of the war."

SOUTHERN CALIFORNIA EDISON COMPANY

The last year was one of material expansion for the Southern California Edison Company, Los Angeles.

Acquisition of various properties makes the company, with its constituents, President John B. Miller writes, "one of the largest in size of the great central-station

systems of the United States." The ramified system serves approximately 1,500,000 population. The electric properties comprise seventeen hydroelectric and eight adjunct steam-generating stations with combined capacity installed of 302,430 hp.

"In general," Mr. Miller says, "we have endeavored to administer the affairs of your corporation along public-spirited, patriotic lines." In addition to the 280 officers and employees who have joined the colors, two directors are "dollar-a-year" men in Washington.

W. A. Brackenridge, vice-president and general manager, notes that the interconnection of systems, putting into fullest use all developed hydroelectric power in Southern California, will result, based on average water conditions, in a saving of 781,000 barrels of oil per annum, equal to 75 per cent of the 1917 oil consumption by these properties.

Power is needed, water powers are running to waste. Mr. Brackenridge declares that to provide for increasing demand the work of completing and placing in operation additional plants "should be undertaken at the earliest possible moment." More than 800,000 undeveloped hydroelectric horsepower is available in watersheds in which the company's principal power plants are located. Immediate necessities could be met by two installations providing 60,000 hp. more for \$8,500,000.

"Their output in substitution for steam power," adds Mr. Brackenridge, "would conserve approximately 1,100,000 barrels of oil per annum during average water years."

At request of the federal Fuel Administrator, the company has signified its willingness to distribute the output of additional small hydroelectric plants of the city of Los Angeles over its system in substitution for steam-plant generation with fuel-oil consumption.

"All necessary and reasonable requests for service received prompt attention," Mr. Brackenridge says, although financial conditions were not favorable for heavy expenditures during the latter part of the year.

While power was in demand from every quarter it is significant that the greatest increase in demand has been for agricultural purposes.

"There is every indication," Mr. Brackenridge states, "that the demand for electric energy for power service in southern California will be unusually heavy in 1918. The agricultural business has been enormously stimulated. The question with the average farmer to-day is, not, Shall electric power be used for pumping water? but, rather, Can electric power be obtained?"

"Along industrial lines every present condition in connection with fuel costs, scarcity of materials and increased operating expenses indicates that electric energy is what every manufacturer wants and must eventually have. Under existing conditions the principal problem for the company will be to obtain deliveries of material and equipment to keep up with the increasing demand for energy which must surely come."

That part of the total load which might, on a war basis, be termed "non-essential" does not exceed 10 per cent, the remaining 90 per cent being for transportation, agriculture, shipbuilding and general manufacture essential to the successful prosecution of the war.

It is necessary, continues Mr. Brackenridge, "to provide for considerable extensions to distributing systems and for additional hydroelectric equipment." Capital expenditures in 1917 were \$3,716,092.

Transformer Inspection as Economic Measure

Chances of Failure Are Decreased if Transformers Are Issued Thoroughly Clean and Dry and with Leads and Bushings Intact—Practical Methods of Caring for Apparatus and Detecting Flaws

THOROUGH inspection of all distribution transformers returned from the lines should be made before they are again issued for service, first to lessen the chance of failure after replacement on the lines, and second to minimize the labor required in making the installation. Chances of failure are decreased if transformers are issued thoroughly clean and dry and with leads and bushings intact. Moreover, it is evident that minor repairs and adjustments can be made better and cheaper in the shop than by the installation crew in the field.

BUSHINGS NEED CLOSE ATTENTION

Bushings should always be carefully examined, as they are a frequent cause of failure. This is particularly true of the higher voltage classes (11 kv. to 22 kv.) owing to their sizes and greater liability to breakage. A break is not always evident from a casual examination, and each bushing should be shaken to disclose any looseness. A broken or loose bushing, especially a primary bushing, should always be repaired before the transformer is again utilized, since it is almost certain to break down in wet weather and may, under certain conditions, cause a burn-out of the transformer windings.

As most bushings are broken in handling transformers after shipping crates have been removed, means should be provided for protecting them. This is especially necessary with the corner bushings of the flaring petticoat type used in transformers designed for moderately high distribution voltages since the insulators project beyond the re-entrant corners in the case. Some companies provide wooden angles which are bolted to the hanger lugs and encircle the bushings, thus eliminating breakage when the transformer swings against an obstruction.

Although more liable to breakage, double petticoat bushings with long leakage surfaces and deep recesses seem to give better service than the straight or corrugated types. The recess seldom becomes entirely filled with oil and dust, regardless of how much the lead may siphon oil. Furthermore, leakage will not occur across the clean surface between the two parts of the shell. On the other hand, the cylindrical types, whether plain or corrugated, usually become coated with dust whenever there is any oil leakage, and breakdown often results.

In renewing bushings in any line of transformers advantage should be taken of the most recent designs that may be accommodated in the outlet holes. Thus it will be found that the early white cylindrical types may in some instances be replaced with corrugated brown glazed bushings, which, having a longer leakage surface, are less liable to break down.

It is important that bushings which are suitable for the service be chosen. Substitutions should not be made unless the new type is superior to the old. A full supply of spare bushings should be carried in stock so that

makeshifts will be unnecessary. A blue-print schedule showing the catalog numbers of primary and secondary bushings required for each tank number should be prepared with the assistance of the manufacturers for each line of transformers handled. This will be found of service both in expediting purchases and in selecting repair parts from store-room stock.

When installing new bushings a grade of sealing compound such as is specially recommended by the manufacturers for this purpose should be used. All of the old compound should be removed before the new bushing is placed. If the bushing is of the type set in with babbitt (those inserted from the outside are usually set in with babbitt, paper lock washers or some similar device), this metal also should be completely removed. In chipping out old bushings and compound provision must be made for catching the scraps to prevent their falling into the coils or bottom of the case. Bushings of the curved styles are best made up complete with leads before insertion in the transformers. The more simple styles, which are easily filled with compound, may be filled in place.

HEATING COMPOUND TO RIGHT TEMPERATURE

Care must be taken to heat the compound to the proper temperature before pouring; otherwise cracks will result. The entire corner of the case in which the bushing is placed should be heated so that the compound will not be chilled on striking the metal. To chill the compound will often result in a leak between it and the case. Much of the oil leakage which occurs around leads and bushings is not caused entirely by siphon action along or through the lead, but may be due to cracks between the bushing and the sealing cement or between the latter and the case. This leakage will not occur unless oil is slopped onto the compound, but it is practically impossible to avoid this in handling a filled transformer. To avoid leaks of this character, not only should hot compound be used, but the surface of the compound above the bushings should always slope in toward the center of the case. This can be effected by tilting the transformer while the compound is being poured as well as while it is hardening. Where the compound must be built up a temporary paper dam may be installed, and after the cement has set it can be removed. This scheme also makes it possible to raise the level of the cement above the top of the bushing so that the bushing and recess may be filled in one operation.

Bushings should be kept clean. It is a good plan to incorporate in all directions covering the installation of transformers a note to wipe bushings carefully after the transformer is in place. Most of the oil and dust which, if left on a bushing, are so likely to cause breakdown are accumulated during transportation from the store room to the job. If the bushings are cleaned after the transformer is hung, this cause of trouble is largely avoided. When transformer tanks are being painted care must be taken not to get paint on the bushings, as

the rough paint surface will tend to gather dust. Bushings of the larger types should be wrapped with cloth or paper while cases are being painted.

HOW TROUBLE WITH LEADS MAY BE PREVENTED

Next to bushings, leads require most frequent attention. They are often broken in handling or are cut short when transformers are removed. In addition, they deteriorate because of the siphoning of oil. Secondary leads of the types of transformers under discussion are invariably rubber-covered. Primary leads are usually rubber-covered, although some manufacturers have recently used varnished cambric insulation for voltages of 11 kv. and up. Each material has its advantages. Rubber withstands weather and moisture well, but it is deteriorated rapidly by oil. This weakness is its most serious defect as oil is often siphoned over the leads. Varnished cambric, on the other hand, while benefited by oil, does not withstand weather well when protected only by a braid covering. It is easily dried out by hot weather and is liable to absorb moisture in wet weather. These remarks apply, of course, only to the leads outside of the case; those inside are always insulated with varnished cambric.

In arranging for shop repairs to transformer leads it is first necessary to prepare a schedule of cables to be used in making renewals, in order to secure uniformity in purchases and repairs. This is preferable to attempting to replace the old lead with one precisely similar in size, insulation and stranding to that installed at the factory, since in the past manufacturers have differed considerably as to these details in transformers having identical ratings. To follow these deviations would require an unnecessarily elaborate stock of cable. A schedule which has proved satisfactory in practice is given herewith for two classes of transformers, for an 11,000-volt and a 2300-volt line. The cables selected, especially those used for primary leads, have not been chosen exclusively on a basis of their usefulness as transformer leads, but also with a view to their use in the wiring of substations and similar work, in order to avoid the carrying of overlapping stocks. All cables are specified as single-braid, rubber-covered. However, if any are to be used extensively in outdoor work, as for instance in wiring between cut-outs and transformers, they may be specified as single-braid and tape. The rubber insulation is 30 per cent Para for the 11-kv. leads and N. E. C. for the others.

It is evident that cable much smaller than No. 6 might be used for the smaller sizes of 11-kv. transformers. However, the expensive part of cable is the insulation, therefore little saving per foot can be effected by ordering a smaller size. Since this size is used extensively in transformer installation wiring, short pieces are usually available for leads which might otherwise be wasted.

The greatest difficulty in installing leads is to prevent the siphoning of the oil. If this happens, the oil will rapidly deteriorate the rubber of the leads and in addition will gather dirt on leads and bushings and thus increase the danger of breakdown. Where the primary terminal blocks are under oil, as is the case in most recent types of transformers, solid conductors may be inserted between terminal block and bushing to prevent the siphoning which would be caused if stranded leads were used. Where stranded conductors are used the

splice between the inside portion of the lead (which is insulated with varnished cambric) and the outside rubber-insulated part, as well as all interstices between strands for a short distance on each side of the splice, should be thoroughly filled with solder.

The splice in primary leads should be placed so as to be completely surrounded by sealing compound, and the short, bare and solder-filled portions on each side of the splice should likewise be covered (Fig. 1). A wrapped splice is generally used. Secondary splices and some of the simpler primary splices are placed above the compound. The varnished-cambric insulation of the secondary should be started above the oil level. After filling a bushing with compound, tape should be wrapped around the outgoing lead at the point where it leaves the bushing to prevent the compound from running out before it has set. After the cement has hardened this tape should be removed; otherwise all the oil which may leak between lead and compound will gather at this point and rapidly eat away the insulation.

FIGS. 1 AND 2—BUSHING CONSTRUCTION THAT PREVENTS SIPHONING; THREE-PART TRANSFORMER TEST REPORT

Instructions should be issued to line crews cautioning them against handling transformers by the leads. Transformers are frequently dragged along the ground or truck bed by the leads or are kept from swinging into the pole when being raised by lines attached to the leads. This practice results in many broken leads and bushings.

When new leads are installed they should be made long. In some types of pole installations one additional foot of primary lead will permit direct insertion of the lead into the primary cut-out without a splice.

Some line foremen make use of the connectors provided on the leads by manufacturers, and use care in handling them; others appear to consider them superfluous and often cut them off. Instructions should be given to use these whenever present, as they are considerable labor savers, especially in the larger sizes, and will give no trouble if properly installed. Any connectors which are not used should be left taped to one of the leads so that they will be available if necessary in some future installation. In removing transformers foremen should be cautioned to cut the feeds between the connectors and the line and not the leads between

the connectors and the transformers. The connectors may then be saved in the shop. Many leads are cut so short through carelessness that they must be replaced before the transformer can be reissued for service.

PAINTING OF CASES AND CARE OF OIL

Cases should be repainted whenever transformers are brought in from the lines, unless they have been installed only a short time. Sheet-steel cases especially will deteriorate rapidly unless protected by paint and if rusted should be given two coats. Before paint is applied it is necessary to clean the case thoroughly with distillate and a steel-wire brush to remove all dirt and oil. A good quality of turpentine asphaltum paint will be found serviceable for this work. If a system of company numbers is in use, numbers should be restenciled on transformer cases as soon as they are slightly obliterated. A white-lead and linseed-oil paint should be used for this purpose. Stencils $2\frac{1}{2}$ in. (6.35 cm.) high may be readily deciphered from the ground, still

before they leave the storeyard; this, however, is not always possible. If the old oil is not removed when transformers are returned from the lines, an inspection should be made to see that the oil is up to the proper level. Schedules of transformers showing tank symbols and quantity of oil required for each line of transformers in service should be readily available. It should be noted that transformers of the same make and type but of different form may require quite different quantities of oil.

CLEANING OF TRANSFORMERS AND DETECTION OF FLAWS

The cleaning of the coils of transformers removed from the lines requires careful consideration, especially if they have been installed a considerable time and sludge has been precipitated by the oil. The elimination of oil deposits from the circulating ducts is particularly essential since their effects are cumulative. By impeding the oil circulation they cause the transformer to overheat with a given load, which in turn

FIGS. 3 AND 4—TRANSFORMER STORAGE YARD WITH CRANE FOR HANDLING APPARATUS AND GRID-COVERED PIT IN WHICH TRANSFORMERS MAY BE LOWERED FOR DRYING OUT

they are small enough so that four or five figures may be placed on the smaller-size cases.

If the transformer has been installed for several years, it is preferable to draw off the oil for testing and treatment as soon as it arrives on the testing platform. On the other hand, if the transformer has been on the lines only a short time and the oil seems clear and without a burned odor, it need not be removed. In the case of the larger sizes of distribution transformers, a sample should be drawn from the bottom of the case with a "sneak" for a moisture test. All transformer oil should be carefully tested, handled and stored in accordance with the recommendations* of the apparatus committee of the National Electric Light Association. Linemen cannot be cautioned too often against handling oil in the open in damp or foggy weather. Companies utilizing distribution transformers of two voltages, as, for instance, 13,200-volt and 2300-volt equipment, will do well to reserve new oil for the higher-voltage equipment and use the second-hand treated and filtered oil in the lower-voltage apparatus.

When possible, transformers should be filled with oil

increases the sediment. An air-transil-oil spray is effective in flushing the ducts. When the oil is drained off it will also clear any moisture which may be present at the bottom of the case.

Many transformers cannot be properly cleaned without removing the coils from the case; this is especially true where the sediment has thickened. Some of the older types of transformers which have no oil ducts between coils should always be removed and cleaned by scraping, as a thick coating is generally to be found on the coils caused by the lack of circulation. Care must be used in scraping to avoid damaging the insulation. An air-distillate spray will be found effective for this kind of cleaning, but should not be used unless the transformer is dried out before being placed in service. A distillate spray should not be used within the test room, owing to the fire risk. A cast-iron grating with removable containers should be provided on the transformer platform for draining coils and cases; otherwise oil will be scattered about (Fig. 4). By this means considerable oil or distillate can be saved as the oil can be filtered for re-use.

Cases should be examined for leaks. A crack in a cover may permit the entrance of sufficient moisture to

*Proceedings N. E. L. A., 1917, Technical and Hydroelectric Section, page 281. Also available in booklet form.

cause breakdown. Cast-iron cases when cracked may be welded with an oxy-acetylene torch; sheet-steel cases may be repaired by brazing or welding. Drain plugs should also be examined and set in with red lead if leaky. Felt strips should be carried in stock so that when those in service are lost or worn they may be replaced. It is important that these be kept effective.

Hanger irons and lugs should be examined for cracks and flaws. When transformers are returned from the lines it is advisable to arrange some system by which the hangers are kept with them or properly marked so that they cannot be mixed with others. If an improper hanger iron is shipped unnoticed with the transformer, it may cause an expensive delay to the line crew.

If a transformer has taps, connecting lugs, nuts and bars should be checked for missing parts. If they are

local shop, or coils may be ordered from the manufacturer. In any case the decision will largely depend on the voltage class of the transformer, its age and type. Antiquated types having operating characteristics inferior to those of modern transformers should seldom be rewound. Transformers of the 2300-volt class can usually be returned to manufacturers for credit on a basis that is more economical than rewinding. On the other hand, it pays to order new factory-made coils for the higher-voltage classes. If a factory repair shop is available within reasonable distance, it may be cheaper to have the factory make complete repairs. When the coils are installed in a local shop, care must be taken to shellac and dry them thoroughly. Some form of drying oven should be available, and the transformer should be placed therein at a temperature of

						100	500,000 e.m.	6	61					

missing, they will usually be found in the bottom of the case, where they were dropped while taps were being changed in the field. Spare connecting links should be taped to leads.

It should be ascertained that coils and core are firmly held in place by the bolts and wedges. To send a transformer out loose in the case will often result in damage to coils and consequent breakdown.

TESTING FOR BURN-OUTS

The most difficult of all repairs are those to coils. When a transformer comes in which is suspected of being burned out, unless it is evident from a superficial examination that the coils are completely ruined, tests should be applied with caution. A breakdown insulation test should never be applied until a megger is used. A premature insulation test may injure a transformer beyond repair. If the megger shows the insulation to be in bad condition, the transformer should be dried out by one of the usual methods and the test repeated. Such a dry-out will often correct the difficulty. Often a careful examination of the coils will reveal only a few damaged turns; these may be replaced or reinsulated if carefully handled. If necessary, all coils should be disconnected so that each may be "meggered" to the core separately. The megger test is of course a preliminary step only for the purpose of trouble location. No transformer should be reinstalled which cannot withstand an appropriate insulation test. Ratio, core loss and exciting-current determinations should also be made on each transformer before it is considered ready.

When it has finally been proved that a transformer is burned out it becomes necessary to decide upon its disposal. Several courses are open: It may be scrapped; it may be returned to the manufacturer on some exchange proposition; new coils may be wound in the

about 85 deg. C. (185 deg. Fahr.) for at least twenty-four hours.

Transformers should be stored in such a manner that they will be easily accessible. If platforms rather than racks are used, ample aisles should be provided between rows to avoid breakage of bushings (Fig. 3). Transformers of similar ratings should be grouped together. Burned-out transformers awaiting disposition should not be mixed with the others, and to eliminate any chance of their being taken out by a repair crew in an emergency they should be given a dash of colored paint or otherwise conspicuously marked.

Some recording system should be adopted in order that transformers returned from the lines shall be assured of proper attention and that no transformer shall be taken out until it is inspected and repaired if necessary. The three-part linen tag (Fig. 2) has been successfully used by one company for this purpose. Upon arrival the yard foreman issues a tag for each transformer. The lowest section is torn off and sent to the shop as a notification of work to be done; the remainder is attached to the transformer. When inspection, repairs and test are completed the middle section is torn off and sent to the record department as a notification of work done, and also that the transformer may be again placed on the active list. The upper portion of the tag remains attached to the transformer until it is reinstalled. The condition of each tag shows at all times the status of the transformer to which it is attached, and regardless of the method pursued in ordering out transformers for use, no transformer will be taken which has not received attention.

STATION & OPERATING PRACTICE

A Department Devoted to Problems of Installation, Operation and Maintenance of Equipment for Economical Generation and Distribution of Electrical Energy

PREVENTION OF SLEET ACCUMULATION ON LINES

The Operation of Conductors at High-Current Density Serves to Melt Sleet—Unloaded Lines Are Heated by Wattless Current

One company in the East has adopted the practice of circulating enough current through its lines during sleet storms to melt any sleet which may adhere to the conductors. Experiments show that about 250 amp. to 300 amp. is sufficient to keep sleet from sticking to 00,000-circ. mil aluminum cables. If ice has already been deposited, considerably more current may be required. Of course, 1 amp. per 1000 circ. mils is maintained only during storms. When the load is light all of the energy is transmitted over one line (duplicate lines being provided), so the conductors in that circuit will be heated sufficiently to melt the ice. The other is connected therewith at the delivery end and a wattless current forced through the cables by the reserve generators.

Lend or Pay Higher Taxes, Which?

HORN GAPS PROVIDED ON TELEPHONE LINES

Used at Frequent Intervals Where Communication Circuit Parallels High-Tension Transmission Line

To relieve the stresses on telephone lines paralleling high-tension transmission lines a Southern company installs horn gaps between the communication circuits

TELEPHONE LINE PARALLELING POWER LINE EQUIPPED WITH HORN GAPS

and ground at frequent intervals. With this construction numerous "safety valves" are offered to high-voltage surges which may be induced in the lines, so

there will not be the tendency to break down insulators. Furthermore, damage to telephone equipment and hazard to persons using it are thus reduced. This additional equipment is relatively inexpensive as the towers are grounded anyway and the horn gaps are easily installed.

CONDENSER RATING NECESSARY TO IMPROVE POWER FACTOR

Method of Using Chart to Determine Rating of Synchronous Condenser Required to Raise Power Factor to Any Value

BY H. H. GETTER

Many times in connection with industrial applications or when correcting distribution conditions it is desirable to have some quick method of determining the synchronous-condenser rating necessary to bring the power factor up to some higher value. The accompanying chart gives this information.

Since most synchronous motors are not designed to carry their total kva. rating in reactive power the chart is intended to give the particular kva. rating of condenser which will change the power factor to any value and also carry 71 per cent of its kva. rating in power load. It is assumed that the power load placed on it is taken off the motors formerly used; in other words, that the synchronous motor is used to replace some of the motors producing the low power factor. In this connection it must also be pointed out that it is assumed that replacing part of the induction motors by synchronous motors will not change the power factor of the remaining induction motor load. The scales on the chart may be multiplied by ten or any multiple thereof if both are similarly multiplied.

To show how this chart is used, suppose the load is 500 kva. at 50 per cent power factor and that it is desirable to increase the power factor to 95 per cent. Follow the 500-kva. ($5 \text{ kva.} \times 100$) circle to the point *a* where it intersects the 50 per cent power-factor line. then drop vertically to the 95 per cent power-factor line. Directly below is the actual kw. load ($250 = 2.5 \text{ kw.} \times 100$). The diagonal distance *de* laid off on the kva. scale indicates the rating ($200 \text{ kva.} = 2 \text{ kv.} \times 100$) of the synchronous condenser which will correct the power factor and also carry a part of the original power load equal to kva. 71 per cent of its rating. The power load it can be made to assume is equal to the projection of *de* on the kw. scale, or 125 kw. (1.25×100). This leaves 125 kw. to be carried by the induction motors.

. As another example of the use of the chart assume that there is a 500-kva. load at 50 per cent power factor and that 250 kw. more load must be carried. By using a synchronous motor to best advantage—i.e., by making the wattless load equal to the power load—how

much can the power factor be improved and what will condenser rating be?

On the vertical line extending from the intersection of the 500 kva. (5 kva. \times 100) circle with the 50 per cent power-factor line lay off with dividers a distance *ag* equal to 250 kw. Point *g* will fall on the radial line indicating the power factor that will be obtained, 80 per cent. The rating of the condenser required to carry the 250-kw. load and raise the power factor from 50 per cent to 80 per cent will be found by laying off the length of the diagonal line extending from 250 kw. on the horizontal scale to the vertical one through 0 on the kva. scale; in other words, 350 kva.

Where replacing part of the induction motors would change the power factor of the induction-motor load the wattless power necessary to improve the power factor can be determined by scaling the vertical distance

CHART FOR DETERMINING CONDENSER RATING NECESSARY FOR CORRECTING POWER FACTOR

between the improved power-factor line and the intersection of the kva. circle and the original power-factor line.

PREVENTING ICE STICKING TO THE TURBINE-RUNNERS

Heating Metal Parts Slightly Above Freezing May Avoid Trouble—Deep Forebays Are Also Found of Benefit for This Purpose

To prevent ice from sticking to the screens, gates and turbine runners it is necessary to keep them at a temperature slightly above freezing. To do this effectively the metal parts must be heated before the gates are opened, for if a coating of ice once forms it will be much more difficult to prevent its building up. Steam, hot-water or electric coils can be placed in contact with the affected part, the metal of the turbine casing and shaft being used to conduct the heat to the surfaces exposed to water. No figures can be given

on the amount of heat which will be required, as two similar plants taking water from the same source have been known to be affected differently.

In the opinion of one turbine manufacturer, a large deep reservoir very close to the turbines will prevent to a great extent the adherence of ice to runners. The greatest trouble occurs where the canal or river is very long and shallow and where there is no pond or reservoir to bring the water to rest and allow it to warm slightly before entering the turbines. The arrangement of penstock intakes also has some effect on the amount of anchor ice which will form. If the ice can be deflected from the opening, the trouble may be reduced.

ITEMIZED COST OF LINE CONSTRUCTION

Data Apply to 35,000-Volt Two-Circuit Line Built Under War Conditions—Based on the Prices Current in 1917

In the accompanying table are given the itemized expenses of building 12 miles (19.3 km.) of two-circuit, 35,000-volt transmission line from Attleboro, Mass., to East Providence. The transmission line, consisting of two No. 00 three-phase circuits of bare copper wire, is erected on 40-ft. (12.2-m.) class "A" chestnut poles, set at intervals of 42 per mile (26 per km.). The cross-arms, which are of hard pine, are 10 ft. 6 in. (3.2 m.)

COST PER MILE OF TWO-CIRCUIT, 22,000-VOLT TRANSMISSION LINE IN NEW ENGLAND

Kind and Size	Quantity	Unit	Price per Unit	Total Cost of Material	Cost of Labor
40-ft. chestnut poles.....	42	Pole	\$10.00	\$420.00	\$126.00
H. D. standard bare No. 00 copper.....	13,000	Lb.	0.335	4,355.00	150.00
Tie wire, No. 4 solid.....	530	Lb.	0.36	190.80
No. 6 arms.....	50	Arm	1.75	87.50	25.00
No. 7 arms.....	50	Arm	1.75	87.50	25.00

Line-wire protector.....	36	Protector	6.44	231.84
Line hardware.....	20.00
Anchor rods and cones.....	60	Rod and cone	1.25	75.00
Cartage.....	150.00
Freight.....	50.00
Total.....	\$6,070.12	\$326.00

Total material and labor..... \$6,396.12

long. Thomas' No. 2118 insulators, supported on Lee No. 9007 pins, are employed. Crossings over streets and other wires are protected by Thomas line-wire protectors. While the line is built to transmit 20,000 kw. at 35,000 volts, it will be operated for the present at a load of 5000 kw. and 22,000 volts.

The estimated cost per mile, including material and labor (exclusive of right-of-way), of the two-circuit overhead 22,000-volt line is \$6,396.12, as set forth in the accompanying table of statistics based upon the prices of 1917.

DESIRABLE CHARACTERISTICS AND FUNCTIONS OF CUT-OUTS

Various Types of Transformer Cut-Outs Are Considered from the Viewpoint of Their Suitability to 2200-Volt to 6600-Volt Circuits

In order to be satisfactory for operation on circuits operating at potentials between 2200 volts and 6600 volts a transformer cut-out must have the following characteristics, said C. A. Harrington of the Mahoning & Shenango Railway & Light Company recently:

1. When operated manually there should be no danger of flash, burn or shock to the lineman. This requirement applies also when re-fusing or re-closing the circuit after an interruption of service.
2. The automatic opening of the circuit in case of overload should be positive and reliable, and should occur while the current is within a few per cent of the rating.
3. The rupturing capacity as well as the current-carrying capacity should be stated by the manufacturer. The rupturing capacity should be several times the normal carrying capacity and the cut-out should break an arc of this magnitude without serious damage to itself.
4. There should be an external and clearly discernible indication of the condition of the cut-out so that it will not be necessary to open the circuit to determine whether the fuse has blown or not.
5. It should be possible to re-fuse the cut-out easily and quickly, even under adverse weather conditions, such as rain or snow.
6. First cost and maintenance cost should be moderate as compared with the value of the equipment protected.

Applying the foregoing tests to existing types of fuses shows that some are not perfect and that the manufacturers have much to accomplish yet. From the standpoint of safety, Mr. Harrington said, it is not safe to open any existing cut out like a disconnecting switch at more than a very small fraction of its rated carrying capacity. As to reliability of calibration, probably those types using specially formed links are best. The use of ordinary lead fuse wire may be sufficiently accurate, however, in the general case. The oil-immersed fuse type of cut-out is about the only type to which manufacturers will give a definite rupturing rating. This type can rupture at least ten times the rated current, they claim.

Expulsion cartridge-fuse type cut-outs have the advantage of giving an indication when they blow, and this indication can be made visible from the ground. Filled cartridge fuses and expulsion fuses inclosed in blocks of insulating material give indications which can be seen on close inspection and without opening the circuit. The common porcelain-plug type cut-out and the oil-fuse type give no indication, Mr. Harrington said.

The re-fusing of practically all types can be made a simple matter if spare removable parts are kept on hand which can be fused on the ground or in the shop. The work on the pole is thus reduced to a minimum, but the troubleman is obliged to carry more apparatus about with him.

The common porcelain-plug type of cut-out of course has the lowest first cost and the lowest maintenance. It is inexpensive even for the smallest sizes of transformers. Next comes the expulsion type having a ribbon fuse within insulating blocks. The cartridge type cut-outs follow, while the oil-immersed type is most expensive of all. The maintenance expense on this latter type is also the highest.

Bonds Speak Louder than Words

SUBSTITUTES FOR COAL AND OIL BEING TRIED

"Hogged Fuel," Pulverized Coal and Natural Gas Are Now Being Used by Pacific Coast Companies in Standby Plants

The high price of California fuel oil and the difficulty of getting coal under present conditions of rail and water transportation facilities has made the Pacific Coast power producers turn to water power. However, all along the coast there was less than normal precipitation in the early part of the winter, and the packed snow or ice in the mountains is less than usual. There will therefore probably be a shortage of stored water in the late summer.

In southern California natural gas is being used to some extent. One company (San Joaquin Light & Power) is building a 26½-mile (43.4 km.) 6-in. (15.2 cm.) pipe to bring in the gas. Central California companies have applications before the Railroad Commission for permission to raise rates, to enable them to meet the expense of coal or oil in auxiliary stations.

In Washington the promising substitute is pulverized coal. The Puget Sound Traction, Light & Power Company has done more pioneer work on this than any other company.

In Oregon the preferred substitute has been "hogged fuel," the material which used to be sent to the refuse burner, but now in increasing quantity is being run through a grinder known as a "hog," which cuts it up into small chunks. This is usually mixed with sawdust, shavings and small chips as they come from the mill machines.

The hogged fuel is sold in "units" of 200 cu. ft. (5.7 cu. m.). A "unit" weighs about 2 tons, fresh from the mill, and is calculated as the equivalent of two barrels of fuel oil, or say 400 kw.-hr.

The Portland Railway, Light & Power Company is trying the experiment of storing hogged fuel in piles to be used during the low-water period of late summer, thereby reducing the use of fuel oil. Two piles, in which 30,000 units are to be stored, are expected to develop, roughly, 12,000,000 kw.-hr.

Formerly refuse burners were maintained by the lumber mills at considerable expense to destroy the large quantities of waste produced. Therefore the use of this waste as fuel not only conserves coal and oil, but also saves the cost of its destruction. As it is bulky material to handle, the power plants are usually placed close to the mills, where conveyors can deliver the fuel direct to the boiler-feed chutes.

The Northwestern Electric Company of Portland is building a steam standby plant adjoining a sawmill which has entered into a contract to supply hogged fuel at a price that would be about the same as fuel oil at 27 cents per barrel. The first unit, now en route, is for 9380 kw. and capacity is to be increased later. In addition to generating electricity, the plant will supply steam to the company's steam-heating system in Portland, delivering 180,000 lb. to 200,000 lb. (81,647 kg. to 90,718 kg.) of steam per hour at 250 lb. (17.6 kg. per sq. cm.) to the main supply line.

CENTRAL STATION SERVICE

A Department Devoted to Commercial Policy and Management
Topics, Including Applications of Electric
Light, Power and Heat

POWER SHORTAGE AFFECTS ELECTRIC RANGE POLICY

Western Property Now Allows But \$20 on Installation Cost, Besides Cutting Down Installment Period from Twelve to Four Months

The plan under which the Pacific Gas & Electric Company of San Francisco formerly sold electric ranges called for 10 per cent cash and the remainder in twelve monthly payments. The company paid the installation cost, which was figured to amount to \$50, and this amount was allowed on all ranges installed on the company's lines whether sold by the company or by outside agencies. If the customer desired to pay cash for the range, a discount of 10 per cent was allowed.

Since the power situation in California has grown acute through the increase in the price of oil, abnormally low stored water supply and rapidly increasing demand for power, the range policy has been revised so that it will no longer be a burden to the commercial department. The present plan is to sell at manufacturers' list less \$20 per range, which is deducted as an allowance on cost of connection; the average installation cost is about \$50, or \$60 including water heater. The terms of payment are 25 per cent cash and the remainder in three monthly payments. If the customer desires to pay cash, a 5 per cent discount is allowed. The connection allowance of \$20 is made only if the range is sold by the company.

The rates remain the same as before (averaging slightly less than 4 cents per kilowatt-hour), and the same service to consumers will be continued. Under the new plan the cost to the consumer will be greater, but it is hoped that the electric range department will be self-sustaining.

Do Your Fair Share—Buy Bonds

EXODUS OF SERVANTS BRINGS BIG APPLIANCE BUSINESS

When New York Manufacturing Concern Took Labor from Homes an Immediate Demand Arose for Labor-Saving Devices

A very interesting evidence of the influence of the domestic-servant problem on the market for electrical appliances was seen last month in Elmira in an experience of the Elmira, Water, Light & Railroad Company. One of the chief local manufacturing concerns lost a large number of young men at about the same time that considerable additional labor was needed in its plant. Much of this labor was required for the operation of automatic machines and for performing other tasks suitable for women. As the local demands on labor have been very heavy for the last two years, there seemed to be small chance of securing men for these jobs. The firm therefore advertised for 600 girls,

giving its appeal a patriotic touch and making a particular effort to secure women who had been in domestic service. There was an immediate response, and a general exodus from the kitchen followed, with the result that hundreds of Elmira families found themselves servantless and compelled to adjust their household methods to the situation.

The Elmira Water, Light & Railroad Company has been actively advertising and selling household appliances for years and has been featuring the electric-servant idea. The influence of this effort was immediately seen, for inquiries began to pile in and there has been an almost continuous demonstration of washing machines, vacuum cleaners and other labor-saving household appliances in the company's salesroom ever since. So acute has been the crisis that the husbands as well as the wives have been taking an active hand in seeking out this household machinery, and a great many of the demonstrations and sales have been made to men. A large amount of business has resulted and the demand continues.

Liberty Bonds Are Safe and Sure

THE SALES MANAGER'S SITUATION IN WAR TIME

Analysis of Tactics of Different Men Confronted with Problem of Reducing Sales Forces for Economical Reasons

The sales manager of a manufacturing company recently made a circuit of a number of important central-station cities in the West and Middle West. In discussing with his firm the impressions gained on the trip he laid special emphasis on the different manner in which different central-station commercial men had met the recent announcements of their superiors that the commercial department would "have to stand a cut."

In his analysis of the tactics of these men under fire he divided them into two classes—first, those who accepted the order unquestioningly and proceeded to discharge their men; second, those who looked at the proposition squarely and met their superiors with an array of sound facts to show the folly of absolutely eliminating commercial work. He had seen and talked to men in both classes and knew how they handled their jobs. His observations and opinions should be of interest and of value to central-station sales managers as presenting an outside viewpoint. The following are approximately his words:

"As typical of those of the second class, take a man in the West who had been spending \$112,000 annually in new-business operations. His profit on that expenditure was \$98,000. In other words, it had actually been costing the company in cash expended \$14,000 a year to acquire all of the load it added to its lines,

including in the term load all power, residence, range and appliance business. The edict was that that expenditure would have to be stopped because of the shortage of capital and because the company did not want to increase its peak materially. The plan proposed by the officers was to curtail the activities of the department by materially reducing the sales forces. But the sales manager demonstrated, first, that 40 per cent of the expense incident to operating the new-business department was not at all new-business expense but was expense incident to keeping existing customers satisfied and on the lines. He assumed, and it was granted, that the company wanted to retain its cordial relations with the public and to retain its existing load. This being true, it was evident that if the entire sales force was disposed of 40 per cent of the cost of running it would need to be expended somehow in order to maintain service. The sales manager contended, however, that the sales department as then organized could do this work better than any other agency. In addition to this he showed how he could by eliminating certain more or less gratuitous services reduce his expenses to \$84,000 and how by extending the duration of certain intensified sales efforts he could increase his profits on sales to \$120,000. He pointed out strongly that the financial stringency was within the company and certainly was not with the potential customers of the company, and that this could be turned to good account by intelligent solicitation of appliance and range business without greatly increasing the peak load of the central station.

"There was considerable doubt as to his ability to increase sales to the extent promised, but nevertheless permission was given to try out the plan. At the rate sales are being made now, the department will make \$147,000 instead of \$120,000 as promised. That gives an indication not only of how well the plan worked but also of the truth of the statement that the public has more money now to spend for electrical goods and service than it ever had before.

"That is the important point which has been all too easily overlooked in the cities where the sales forces were peremptorily discharged. Activities were stopped just at the time when the least effort was required to make sales. In such cities it is notable that the public relations of the central-station companies are none too desirable. This is traceable largely to the fact that the company has no commercial force with which to placate the complaining customer. With him a trivial grievance that could at one time have been glossed over with a jolly word has grown to a deep-rooted grudge that it will take years of effort to eradicate.

"Now, the big thought back of these two different methods of meeting a situation is that the one sales manager knows his job and the other is incompetent in certain respects. The one realizes that the sales manager's job is to advise accurately on commercial policy as well as to see that goods and services are sold. The other sees only that part of his duty which involves the actual selling. The former type of sales manager is certainly the more desirable, for even though he may be less expert at selling, he will get farther in the long run."

LONG INTERCITY HAUL WITH ELECTRIC TRUCK

Five-Ton Truck with Load Makes the Trip from New York to Baltimore Over Very Bad Roads and Arrives in Good Form

As a result of the abnormal conditions of rail transportation the use of trucks for intercity haul is receiving the support of government officials and trade generally. The electric truck is hardly considered as suitable for this type of service, but the accompanying data indicate that it can overcome the difficulties in the way.

A 5-ton truck consigned to the American Tobacco Company in Durham, N. C., by the General Vehicle Company was denied all shipping accommodations east of Washington, and it was found necessary to drive it over the road to Alexandria, Va., then ship it by boat and rail to its destination. As the embargo affected other merchandise also, the truck was loaded with seventy-five cases of tinfoil for a branch of the

ELECTRIC TRUCK EN ROUTE FROM NEW YORK TO BALTIMORE

tobacco company in Baltimore and made the 226-mile (363-km.) trip successfully late in March, notwithstanding the bad road conditions and poor charging facilities en route. After delivering its load the truck made the 38-mile (61-km.) run from Baltimore to Washington on one charge and in good running time.

The heavy traffic over the roads of New Jersey, Pennsylvania and Maryland at the present time has played havoc with the road surfaces in many sections of these States, and when a truck gets mired in a bad spot it frequently ties up scores of other trucks for hours. Some idea of the condition of these roads, particularly in Delaware and Maryland, may be gathered from the fact that this 5-ton truck, which on city streets requires a current of 9 amp. per mile, consumed 240 amp. in going 12 miles (19 km.) in Delaware, or 20 amp. per mile.

On its trip the truck encountered charging conditions anywhere from 90 volts to 140 volts and at from 10 amp. to 110 amp. The forty-four-cell, nineteen-plate battery had a rating of 298 amp., but 380 amp. was taken from the battery in one case and full charge in Baltimore took 420 amp. Neither motor nor battery, it is stated, was heated during the trip, though the current draw was excessive for hours at a time.

Join the Army of Bondholders

COMPARING GAS SERVICE AND ELECTRIC SERVICE

Aspects of the Competition Between the Two Commodities Analyzed by One Who Has Been Studying the Situation

In a paper presented before the Indiana Gas Association, C. N. Chubb, formerly manager of the South Bend district of the Northern Indiana Gas & Electric Company, tried to convince the gas men that they had electric competition in every line of their business.

He pointed out that in the electrical industry half a dozen large companies do national advertising, and that in the gas field no such work as this goes on to keep the consumers of public-utility service thinking about the gas company as they think about the electric company.

"In the lighting field," Mr. Chubb said, "the electric man has not only developed efficient lamps but has developed artistic fixtures and lighting effects. He has also made electric lighting convenient for use and easy to maintain, with the result that consumers are willing to pay more for electric service than for equivalent gas service. The convenience and easy-maintenance problems are the hardest for the gas man to meet in lighting." The same holds true in the small domestic-appliance field, the speaker said, lamenting particularly that the gas industry had not sooner appreciated the value of auxiliary outlets.

Speaking of cooking, he said that the electric range does not have to go through the educational period, for the public is ready to take up electric cooking just as soon as it can be convinced of the practicability of the electric range. The electric range is advocated as easy of operation and control by means of automatic heat regulators and time-limit devices, heatless and odorless because of good insulation, and economical owing to better efficiency. Easy control, said Mr. Chubb, is certainly an advantage which should be shared by the gas range. The speaker further pointed out that the electric range is more efficient than the gas range, and declared that gas-range manufacturers should build more efficient gas ranges even at a greater expense.

In his review of the industrial field Mr. Chubb said that the gas industry had been content to let its customers struggle along with inefficient apparatus until the various fields were invaded one by one by the electric companies. As the situation now exists, the gas industry stands to lose considerable industrial business which it might have retained by beginning earlier to develop efficient utilization apparatus.

Giving Wider Publicity to Federal Viewpoint on Utilities

On a pink folder which is 3 in. by 5 in. in dimensions the Commonwealth Edison Company of Chicago has mailed to its customers copies of the letters on the importance of public utilities recently exchanged between President Wilson and Secretary of the Treasury William G. McAdoo. This folder is being distributed to the customers of the company with the idea of giving more widespread publicity to the viewpoint of the federal government on the utilities as essential factors in the national welfare.

STOP FLAT-RATE SERVICE TO PREVENT ENERGY WASTE

Worcester Company Feels that Uncertainties of Fuel Situation Demand Utmost Economy in Use of Electricity

On April 1, 1918, the Worcester (Mass.) Electric Light Company discontinued flat-rate service on its system, about 900 customers going over to the metered basis. All of these were residence customers, the commercial flat-rate service to stores and other business establishments having been done away with several months before. Practically no complaint was received from the residence customers, whose monthly bills on the flat-rate plan ranged in general from \$1 to \$3. The company announced the change when it mailed its February bills, each bill carrying a 1¾-in. by 5½-in. yellow sticker as reproduced herewith.

To the local press representatives officials of the company explained that under the old flat-rate plan considerable energy was being wasted. War conditions demand the elimination of all unnecessary waste, and the anticipated uncertainties of the fuel situation later

ALL FLAT-RATE CONTRACTS WILL BE DISCONTINUED APRIL 1, 1918

We will install a meter for you and charge you in future for our service at our regular lighting rates. Some meters will be installed before April 1 to enable us to complete all changes as near that date as possible. Should your meter be installed earlier we will gladly rebate any amount you may have paid in advance for your service.

Yours truly,

WORCESTER ELECTRIC LIGHT COMPANY

March 1, 1918

11 Foster Street

in the year require the utmost economy in the utilization of electricity. The company also wished to do away with the maintenance of current-limiting equipment used in connection with flat-rate installations. Then, too, a good deal of time and trouble had been experienced in connection with trips to homes to sign up new contracts for small increases in connected load. The time of year was favorable to the change, with a decreasing consumption of energy for lighting purposes. The flat rates were inaugurated about six years ago, when the company's residential lighting rate was about 12 cents per kilowatt-hour, while the present rate is 8 cents. The flat-rate plan was based on a charge of 1 cent per watt connected per month.

In order to make the change as easily as possible, customers were informed that if a meter should be installed during the month before the first of April customers desiring to go over to metered service then and there would be allowed to do so; but if any one wished to retain his flat-rate service until April 1, the reading of the meter on that date and not on the date of setting would mark the beginning of the new system of charging. In many cases the change to the metered rate was accepted on the spot, the public taking the company's explanation without objection. Data are not yet in hand as to the total effect of the change, but it is known that many customers' bills will be no larger under the metered rate than on the flat rate.

TECHNICAL THEORY & PRACTICE

Including a Digest of Important Articles Appearing in
the Scientific and Engineering Press
of the World

Generators, Motors and Transformers

Replacing Direct-Current and 25-Cycle Alternating-Current Motors by 60-Cycle Designs in an Industrial Plant.—Operating results have shown that the total cost of the installation will be recovered in a few years through increased production and economies effected by standardizing motor drive and change in service arrangement to use three-phase, 60-cycle, 440-volt alternating-current motors and power purchased from a central-station company in replacing the original equipment, which consisted of steam and gas-engine-driven generating units, furnishing 125-volt direct-current and 25-cycle alternating current service to different parts of a plant.—*Electrical Record*, April, 1918.

Rotary Converters.—Self-starting two-phase and three-phase rotary converters are described and their wiring diagrams are shown.—*Southern Engineer*, April, 1918.

8750-Kva. Compounded De Laval Turbo-Generator at Vasteras.—The nickel-steel rotor is forged in one piece, the windings being held in place by long wedges. Provision is made for the inlet of ventilating currents below the windings. Illustrations accompany the description.—*London Engineering*, March 29, 1918.

Mechanical Design and Specification of Turbo-Alternator Rotors.—S. F. BARCLAY.—Stresses in the solid and laminated types of rotor are discussed. The desirability of high-tensile strength and cold working, also the relative mechanical and electrical features of nickel-chrome steel and solid forged carbon-steel rotors, are discussed.—*London Electrical Review*, March 29, 1918 (abstract of paper read before the Institution of Electrical Engineers).

Aluminum in Transformers.—Aluminum has been suggested as a substitute for copper in transformer windings. Dealing with heat dissipation, temperature rise, comparative costs of the different materials and other important factors, it appears that the advantages are still with copper.—*London Electrical Review*, March 29, 1918.

Armature Reactance of Polyphase Alternators.—F. S. NEWBURY.—Drop in voltage due to an increase in load is caused by three factors, viz., the resistance of the armature winding, the reactance of the armature winding and the armature demagnetization or reaction. These factors are discussed in reference to polyphase alternators, the article embodying several useful illustrations.—*Electric Journal*, April, 1918.

Lamps and Lighting

Electric Lighting of Ecclesiastical Buildings.—WILLIAM WILSON.—There are few tasks so difficult as that of providing suitable artificial lighting for a church or cathedral, says the author. It involves the introduction of what is virtually a novelty into one of the most

conservative situations in existence. The article deals with the special advantages of electricity for church lighting, the requirements to be met, electric fittings, and the general details pertaining to the subject.—*Journal of the Institution of Electrical Engineers*, March, 1918.

Incandescent Lamps.—H. W. MATEER.—Data relating to the different kinds of lamps, color quality of light and the effect of improvements are discussed in this article.—*Toronto Electrical News*, April 1, 1918.

Generation, Transmission and Distribution

Transmission-Line Practice.—LIEUT. E. T. DRIVER and E. V. PANNELL.—Sixth article on this subject, dealing with some high-voltage problems. Conductor spacing is the principal subject discussed.—*Toronto Electrical News*, April 1, 1918.

Electric Power Supply and Coal Conservation.—To improve transmission and distribution conditions in England the following plans are proposed: (1) the establishment of a central body of electricity commissioners; (2) the division of the country into districts; (3) the appointment of boards to control the generation and transmission in these districts, leaving the detailed distribution of electricity and sale of electrical energy more or less in the hands of existing authorities; (4) the installation of large power plants in order to obtain the maximum economy in capital outlay, efficiency in operation and diversity of demand; (5) the provision of extra high-tension mains which should interconnect the various stations.—*London Electrical Review*, March 22, 1918.

Double Overhung Francis Turbines.—ARNOLD PFAU.—The article deals with use of large single hydroelectric units, particularly the double overhung Francis turbine, which is used in the White Salmon River powerhouse.—*Journal of Electricity*, March 15, 1918.

Electrical System of the Rand Power Companies, with Special Reference to Methods of Operation and Experience.—BERNARD PRICE.—Use of cables in series with overhead line, running up rotary condensers, temperature rise of generators, cooling of transformers, steam governing, generator relays and use of generator transformers as coupling transformers are among the subjects discussed in this paper, which refers particularly to methods of operation.—*Transactions of the South African Institution of Electrical Engineers*, December, 1917.

Interconnection and New Power Development.—P. M. DOWNING.—There is an abundance of undeveloped hydroelectric power on the Pacific Coast, where it could be economically transmitted to markets, says the author, but it has been permitted to lie idle for no other reason than that capital could not be interested in its development. These projects are unattractive not because of physical or engineering reasons, but solely because their development and utilization are

unattractive financially.—*Journal of Electricity*, March 15, 1918.

Water Power in Bavaria.—Two companies have been formed in Bavaria for the purpose of developing the water powers of the kingdom, one on the upper Inn and the other on the middle Isar. One section of the latter—between Mossburg and the Danube—has been turned over to the Allgauer Elektrizitaets Gesellschaft, which is providing for about 70,000 hp.—*Journal du Four Electrique*, March 1, 1918.

Tamarack Mills Power Plant.—CHARLES H. BROMLEY.—The chief features of a new oil-burning plant furnishing light, heat and power to the Tamarack Mills, Pawtucket, R. I., are discussed. Some interesting performance figures are given.—*Power*, March 26, 1918.

Physical Data of a High-Voltage System.—H. A. BARRE.—The article deals with the Big Creek hydroelectric development and transmission system of the Southern California Edison Company, one of the most impressive systems of high-voltage transmission in existence. The article will be found of timely interest in these days of interconnection and hydroelectric conservation. Valuable data on high-tension design, standard anchor and angle tower construction, steel-cored aluminum cable, ground wires, insulators, routine tests, etc., are given. The specification details involved in this article are of especial value.—*Journal of Electricity*, March 15, 1918.

New Station of the Rochester Company.—P. B. FINDLEY.—The article deals with a 32,000-hp. hydroelectric generating station operated to carry the load peaks of the combined systems. It describes the location and general scheme of the station, the dam and gate construction and hydraulic and electrical features of the plant.—*Chicago Electrical Review*, March 23, 1918.

Traction

Locomotives for the St. Paul Railway.—F. H. SHEPARD.—The article deals with the construction of ten Baldwin-Westinghouse locomotives for the Chicago, Milwaukee & St. Paul Railway, gives a method of minimizing rheostatic losses, explains how three sources of supply can be provided for the auxiliaries, and outlines considerations favoring the twin-motor quill drive over other kinds of motors.—*Electric Railway Journal*, March 23, 1918.

Fast Service Line.—The system extends from Niagara Falls to Buffalo, operates at 600 volts and cost approximately \$170,000 per mile. Features of the overhead construction and substations with cost data are set forth in this article.—*Toronto Electrical News*, April 1, 1918.

Savings Effected by Automatic Substations.—H. E. DAVIS.—Light-load losses are minimized by stopping the rotary converters during prolonged light loads. The automatic substation permits three-car trains to pass without overloading the machines. The article describes the New York State Railways (Utica-Syracuse lines) system, which purchases automatically controlled energy for its Manlius Center substation.—*Electric Railway Journal*, April 13, 1918.

Why the Automatic Substation Saves Materials and Labor.—CHARLES F. LLOYD.—Advantages and disadvantages of automatic substations are analyzed, the

article describing details of equipment and referring to economies that can be effected.—*Electric Railway Journal*, April 13, 1918.

Installations, Systems and Appliances

Automatic Switching Equipment.—R. J. WENSLEY.—This article deals with the automatic operation of synchronous substations, taking up starting, polarity, synchronism, protective devices, etc.—*Electric Journal*, April, 1918.

Electrical Shoemaking.—G. BASIL BARHAM.—One of the first shoe factories in the world to be electrically equipped throughout is described.—*London Electrical Review*, March 8, 1918.

Overwinding and Controlling Devices for Winding Engines.—H. NEWBURY.—A discussion of the relative merits of the different types of winding engines that goes into detail of the conditions to be met and how they should be met.—*Transactions of the South African Institute of Electrical Engineers*, November, 1917.

Water Pumping by Electric Power.—R. L. YATES.—This is the continuation of an article which discusses the characteristics of motor-driven pumps and gives suggestions for selection of pumps for municipal water pumping. The author points out that economies in plant operation and efficiencies of the pumping equipment used do not necessarily parallel each other. The efficiencies of reciprocating pumps are, as a general rule, in excess of the efficiencies to be obtained by the use of centrifugal pumps. The comparative efficiencies of triplex and centrifugal pumps operating under the best conditions and for capacities up to 1500 gal. (5678 l.) per minute are discussed.—*Chicago Electrical Review*, March 23, 1918.

Warrior River Steam Plant of Alabama Company.—W. B. WEST.—Brief description of a stand-by steam station for taking care of emergency loads. One 25,000-kw. turbo-generator unit is installed, but additional units are to be provided. Coal is obtained from a mine only a few hundred feet distant. Details of the layout and other interesting features are given.—*Power*, March 19, 1918.

Wood, Steel and Concrete Pole-Line Costs.—F. L. HAUSHALTER.—The comparative costs of treated and untreated wood poles are discussed in this article, which is a continuation of an article in the April 6 issue.—*Chicago Electrical Review*, April 13, 1918.

Practical Alternating-Current Engineering Problems.—W. R. BOWKER.—Different methods of interconnecting rotary converters and transformers, also their operating characteristics, are discussed. The article embodies several circuit diagrams.—*New York Electrical Engineering*, April, 1918.

Standardization of Pin-Type Insulators.—L. M. KLAUBER and R. E. CUNNINGHAM.—The standardization of supplies and the consequent cost reduction, improved service and economies resulting therefrom are described in this article.—*Journal of Electricity*, April 1, 1918.

Wires, Wiring and Conduits

Mechanical Working of Underground Cables.—CHARLES F. STREET.—The mechanical strength of the hauling tackle and also of cable, including a determination of the force required to draw cables of varying dimensions into different classes of ducts, the ability of

lead-covered, air-spaced and paper-core cable to withstand a tensile force without injury and the relative properties of lead and an alloy of lead and tin as a sheathing material, are discussed.—*Telephone Engineer*, April, 1918.

Electrophysics and Magnetism

Simplest Hardening Equipment for Carbon Steel.—At a certain temperature, called the temperature of recalescence, carbon steels become non-magnetic. The temperature at which this condition occurs is also the temperature at which carbon steels should be quenched in order to obtain the finest grain and most desirable mechanical properties in the hardening metal. Thus, in order to obtain an indication of the best temperature for quenching, it is only necessary to have an indication when the steel becomes non-magnetic. A description and an illustration of the furnace embodying this principle are given in the article.—*London Electricity*, March 22, 1918.

Electromagnetic Induction and Relative Motion.—S. BARNETT.—A paper was presented before the American Association for Advancement of Science on this subject in which the author considers a short-circuited parallel-plate air condenser in a magnetic field parallel to its plates. If the condenser is moved parallel to the plates but at right angles to the induction, certain conditions will exist, whereas others will exist if the condenser is held stationary and the agent producing the magnetic induction is moved parallel to the plates but at right angles to the induction. A very complete discussion is given of the results observed that may clear up hazy ideas regarding the generation of electromotive forces by motion of conductors in a magnetic flux.

Units, Measurements and Instruments

Measurement of Permeability.—FRANK SHAW.—Permeability is influenced by the layer of scale formed on mild steel during the process of rolling. A number of experiments are described that were conducted to determine the permeability of laminated specimens of steel by the Ewing double bar and yoke method.—*London Electrician*, March 22, 1918.

Telegraphy, Telephony and Signals

New Swedish Radio Station.—At Karlsborg, Sweden, a wireless station has been completed which is capable of sending messages over a distance of 3150 miles (5000 m.). The masts, weighing only 25 tons each, are 684 ft. (210 m.) high. They are insulated at four different places from base to top and are erected with the bases embedded in black granite blocks, impregnated with paraffin. The antennas are 1476 ft. (450 m.) long and composed of sixty phosphor-bronze wires hung from steel tubes. The capacity of the station is increased by covering the territory between the masts with a phosphor-bronze wire netting.—*Schweizerische Bauzeitung*, Feb. 9, 1918.

Inclosed Arc with Novel Characteristics.—The device consists of a low-expansion glass envelope such as a sodium-magnesium boro-silicate glass. The cathode consists of a high refractory material such as tungsten, tantalum or carbon. The anode is made up of metallic calcium, magnesium, titanium or other metal highly reactive chemically to gases other than the inert so-called rare or monatomic gases. Certain chemical

effects and electrical effects are dealt with in the article.—*Wireless Age*, March, 1918.

Transmission Efficiencies of Cord Circuits.—WALTER C. FREEMAN.—The efficiencies of different kinds of cord in operation upon different kinds of circuits are discussed. The article is illustrated with circuit diagrams.—*Telephone Engineer*, April, 1918.

Loading Coils Versus Repeaters.—W. N. FURTHMANN.—Properly designed and correctly installed loading coils are adequate for all long-distance work, says the author. The reasons for arriving at this conclusion are embodied in the article.—*Telephone Engineer*, April, 1918.

Miscellaneous

Combustion Characteristics of Coal and the Selection of Suitable Stoker Equipment.—JOSEPH WORKER.—Many factors that enter into the success or failure of equipment selected for various kinds of coal are discussed. The article is well illustrated and contains considerable data on the various effects of coal and also on the performance of various kinds of stokers.—*Electric Journal*, April, 1918.

New Insulating Material.—A new composition proposed as a substitute for porcelain, marble, slate and vulcanized fiber, etc., consists of 52 per cent pulverized asbestos, 14 per cent of sifted mica, 20 per cent mineral caoutchouc, 10 per cent rubber solution, 3 per cent of sulphur and 1 per cent of resin. It is claimed that the finished material is hard and nearly fireproof, and that it can be molded, machined and wrought.—*London Electricity*, March 22, 1918.

Water Power in Great Britain.—ALEXANDER NEWLANDS.—Data relating to the rainfall, river discharge, ratio of ordinary to flood discharge, catchment areas, horsepower available, etc., in the British Isles, with references to many available sources of information on these points, are embodied in this article, which is an abstract of a paper read before the Royal Society of Arts.—*London Electrical Review*, Feb. 8, 1918.

New Views of the Combustion of the Volatile Matter in Coal.—S. H. KATZ.—The volatilization of the hydrocarbons in coal and the burning of the volatile matter in the combustion space of the furnace are discussed in the following order: (1) physical influences of the chemistry of volatilization of coal matter; (2) primary products of distillation; (3) mechanism of the combustion of hydrocarbons, which includes the speed of the reaction, with a table giving the cracking effect of temperature on oil at atmospheric pressure, and finally the hydrocarbon equilibrium in coal fires.—*Technical Paper* 183, Department of the Interior, Washington, D. C., 1918.

Description of the Works of White's South African Cement Company, Ltd.—H. CAMPBELL.—The article gives interesting details in connection with the power plant and certain statistics pertaining to the laboratory, repair shops, limestone quarry, ropeway, wet mill, mixer, kiln plant, coal plant, cement mills, silos, etc.—*Journal of the South African Institution of Engineers*, January, 1918.

Fuel-Oil Burners.—J. F. SPRINGER.—Essentials of the two principal methods of burning oils and details of the equipment are described.—*Southern Engineer*, April, 1918.

NEWS OF THE INDUSTRY

Chronicle of Important Events and General Activities
in the Technical, Commercial and
Manufacturing Fields

ENERGY SUPPLY FOR MUNITION FACTORIES

President Joseph B. McCall Says that Philadelphia Electric Company Furnishes More for War Industries than Any Other Utility

Reporting concerning the operations of the last year, Joseph B. McCall, president Philadelphia Electric Company, says that stockholders will be interested in knowing that the company, in addition to supplying the general needs of the communities served, is now furnishing more energy to munition factories and other war industries than any other utility in the United States and is second in supplying transportation.

"The electrical energy for all additional transportation requirements for Hog Island and other points supplied by the Philadelphia Rapid Transit Company and the additional electrification of the Chestnut Hill branch of the Pennsylvania Railroad are furnished by this company," says Mr. McCall.

A "WINNING THE WAR" N. E. L. A. CONVENTION

President Lieb Calls Attention to the Fact that the Atlantic City Meeting Will Be Devoted Entirely to War Problems

President John W. Lieb of the National Electric Light Association has sent the following notice to members:

The thirty-fourth annual meeting of the National Electric Light Association and its forty-first convention, to be held at the Hotel Traymore, Atlantic City, June 13 and 14, 1918, will be devoted entirely to problems of the war.

This will be a strictly business meeting, without entertainment of any kind. It will concern itself entirely with the vital problems of the industry arising out of the war, toward the winning of which the thoughts and energies of every public utility must be consecrated.

No papers will be read. Reports from committees and individuals and discussions will be confined to matters of major importance, and the brief two days will allow no time for the usual helpful discussions on general topics relating to the progress of the art. Everything said and done must be keyed to a victorious conclusion, and an early one, of the great struggle on which our nation has entered and in which our industry is taking a part of continually growing importance.

There will obviously be a reduced attendance, far below the numbers in pre-war years. Naturally, member companies, large and small, will endeavor to be represented by at least one of their officers or executives; and others in attendance would preferably be selected from among those dealing directly with the member company's activities affecting war work or civilian co-operation with the national government.

Our industry, increasingly a permeating factor in the national life, is now subjected to abnormal strains on its personnel and resources. It is the desire at such a vital juncture to devote the time and energies of the association and of those at the convention to only one enterprise which now counts—winning the war.

LIGHTLESS ORDER SUSPENDED BY FUEL ADMINISTRATION

Dr. Garfield Withdraws Restrictive Regulations Until Sept. 1 at the Urgent Request of the Liberty Loan Committee

United States Fuel Administrator Garfield sent to all state fuel administrators on April 22 an order suspending until Sept. 1 the so-called lightless night order which went into effect last November, when extraordinary street and sign lighting was prohibited on Thursday and Sunday nights of each week. The order is:

"At the urgent request of the Liberty loan committee I have decided to suspend operation of the lightless night order beginning next Thursday night. [The lightless order was therefore suspended beginning April 25.—Eds.] By reason of the late hour of lighting brought about by the daylight saving law the lightless night order will remain suspended until Sept. 1 next, when it will again become effective."

Reports to Washington say the restrictions throughout the country on lighting, etc., have been modified by the state fuel administrators from time to time as weather conditions changed. Many of the modifications have been of purely local interest and have been dealt with in detail by the various state administrators.

Aiding the Sale of Liberty Bonds Electrically

During the Liberty loan campaign at Chicago a unique method of acquainting riders in automobiles with the progress of the local drive was worked out. A space on a North Side boulevard was marked off to represent Chicago's quota of bonds. As the sales force progressed with the sale a ball was moved over this marked section by an interval representing the number of thousands of dollars' worth of bonds sold. The ball was electrically lighted at night.

MEETING IN NEW YORK ON
PUBLIC UTILITY CONDITIONS

Conference Held by the Committee with Advisory
Committee Representing Electric, Gas and
Electric Railway Properties

A meeting of the National Committee on Public Utility Conditions was held in New York on April 18. It was called for a conference with the advisory committee. The National Committee on Public Utility Conditions is composed of P. H. Gadsden, E. K. Hall and H. H. Crowell.

The advisory committee consists of:
Representatives from National Electric Light Association—J. W. Lieb, New York Edison Company; Joseph B. McCall, Philadelphia Electric Company; Henry L. Doherty, Cities Service Company, New York.

Representatives from American Gas Institute and National Commercial Gas Association—Randal Morgan, United Gas Improvement Company, Philadelphia; A. P. Lathrop, American Light & Traction Company, New York; M. B. Daly, Eastern Ohio Gas Company, Cleveland.

Representatives from American Electric Railway Association—T. N. McCarter, Public Service Corporation, Newark, N. J.; L. S. Storrs, Connecticut Company, New Haven, Conn.; A. W. Brady, Union Traction Company of Indiana, Anderson, Ind.

Mr. Lieb has been elected temporary chairman of the advisory committee and T. C. Martin temporary secretary.

The National Committee on Public Utility Conditions is the committee which presented recently the facts showing increased costs of operation and the need of higher rates to officials of the Treasury Department, through whom they were referred to President Wilson.

This committee, composed of representatives of electric, gas and electric railway properties, will represent the utilities associations on matters common to the entire industries. It is not the intention to handle matters affecting individual companies.

Employees of New York Companies Doing
Their Share

Between 600 and 700 employees of the New York Edison Company in the Bronx district and of the Yonkers Electric Light & Power Company held a Liberty loan rally at 140th Street and Rider Avenue on April 22. Frank W. Smith, vice-chairman of the committee carrying on a campaign for bond subscriptions among the employees of the Consolidated Gas and affiliated gas and electric companies, presided. Addresses were made and the orchestra of New York Edison Company employees rendered several patriotic selections. The audience sang the "Liberty Anthem." Although 80 per cent of the audience had already subscribed, \$5,000 more was turned in. This brought the total subscriptions in the affiliated companies to \$870,000, with 11,607 employees out of 14,265 subscribing.

Congress to Consider Further Taxation Soon

Representative Kitchin, chairman of the House ways and means committee, during a debate in the House of Representatives, announced that Congress must soon consider whether further taxes are to be imposed.

ELECTRIC & MANUFACTURING COMPANY

LARGE TOTAL OF BUSINESS OF GENERAL ELECTRIC COMPANY

Electrical and Mechanical Orders in 1917 Reach
\$246,700,000 and Sales Billed Aggregate
\$196,900,000 in the Year

"In the year 1917 the volume of your company's business far exceeded that of any previous year," is the modest statement of C. A. Coffin, chairman of the board of the General Electric Company, in the annual report to stockholders. Values of orders received, compared with preceding years, were:

	Electrical and Mechanical	War Munitions	Total
1917.....	\$246,778,491	\$246,778,491
1916.....	167,169,058	\$2,416,000	169,585,058
1915.....	98,385,891	33,980,000	132,365,891
1914.....	\$3,748,521	\$3,748,521
1913.....	111,819,142	111,819,142

The value of electrical and mechanical orders received last year increased 47.6 per cent over 1916 and 150.8 per cent over 1915.

Sales billed, \$196,926,318, increased 47 per cent over the previous year. Earnings compare as follows:

	Year Ended Dec. 31		
	1917	1916	1915
Sales billed	\$196,926,318	\$134,242,289	\$85,522,070
Less: Cost of goods billed. Including all operating, maintenance and depreciation charges	167,921,778	118,948,198	76,898,183
Balance	\$29,004,540	\$15,294,091	\$8,623,887
Interest and discount....	\$1,433,317	\$1,539,499	\$1,434,269
Income from securities owned	2,661,150	1,844,645	1,554,843
Sundry revenues	417,322	482,738	694,996
	\$4,512,289	\$3,866,882	\$3,684,108
Total	33,516,829	19,160,973	12,307,995
Less: Interest on debentures	571,645	571,445	570,085
Interest and discount on notes payable	541,356
	\$1,113,001	\$571,445	\$570,085
Balance	\$32,403,828	\$18,589,528	\$11,737,910
Less excess profits tax estimated	5,500,000
Available for dividends..	\$26,903,828	\$18,589,528	\$11,737,910
Dividends paid	*11,165,882	8,121,646	8,129,918
Net surplus for the year..	\$15,737,946	\$10,467,882	\$3,607,992
Previous surplus.....	34,160,753	23,692,871	20,084,879
Surplus	\$49,898,699	\$34,160,753	\$23,692,871

*Includes 8 per cent cash, 1 per cent cash "Red Cross" and 2 per cent stock.

Mr. Coffin says in part in the report:

A substantial portion of the large increase for the past year consisted of orders for ship propulsion and other apparatus placed by and for the United States government, but the increase extended to nearly every line of the company's product. Higher prices, due to increased cost of material and labor, were also a factor in the larger total value of orders.

The large increase in sales during the last two years has made it necessary to add to manufacturing facilities to an extent entirely without precedent. During the year \$22,320,895 was expended for land, buildings and other structures, tools, machinery and smaller equipment and fixtures. In view of the prevailing high prices of all material and other unusual conditions, the sum of \$13,287,249 has been charged against income and general reserve as depreciation and additional plant reserves, resulting in a net in-

crease, in the book value of plant and equipment, of \$9,033,646.

Although previous reports to the stockholders have only shown the net book value of the plant account, it has been the company's practice for years to maintain a record of the cost of property investments, confirmed by a careful appraisal. The difference between the gross and net book values has been carried on the general ledger in a "general plant reserve." It is now deemed desirable to set forth both items in the published report.

The large increase in the volume of orders naturally involved corresponding increases in merchandise inventories and in customers' notes and accounts receivable.

After deducting reserves which are regarded as ample the merchandise in factories, district warehouses and elsewhere is shown at a net book value of \$81,851,310, an increase of \$30,690,671 for the year.

Customers' notes and accounts receivable, after deducting adequate reserves, are carried at a net book value of \$38,406,993, which is \$11,590,695 more than the balance outstanding at the close of 1916.

The additional capital absorbed in plant extensions, inventories and customers' accounts amounted to \$77,602,262, in order to provide for which in part the company issued short-term notes during the year, the balance outstanding at Dec. 31 being: Issue of July 2, 1917, three-year 6 per cent notes, \$15,000,000; issue of Dec. 1, 1917, two-year 6 per cent notes, \$10,000,000; temporary notes, maturing in February and May, 1918, \$2,757,721; total, \$27,757,721.

It is expected that with the return of normal business conditions sufficient cash will be released by a reduction in inventories and customers' notes and accounts to provide for the two note issues aggregating \$25,000,000.

The federal taxes for 1917, including the income tax at 6 per cent, \$1,789,508, which was absorbed in cost of sales, and the estimated excess profits tax of \$5,500,000, will amount to \$7,289,508.

On May 8, 1917, Anson W. Burchard, vice-president, was elected a director of the company.

The board of directors desires once more to testify to its deep appreciation of the admirable response of the employees in all departments to the demands made by the difficult and pressing problems of the past year.

Mr. Coffin then takes up the increase in capital stock. None had been made since 1912, and in the meanwhile the growth of the business had been:

	1917	1912
Orders received	\$246,778,491	\$102,934,788
Sales billed.....	196,926,318	89,182,185
Net income (after all taxes) applicable to interest and dividends.....	28,016,830	13,110,823
Total surplus (after payment of interest and dividends), represented by investments in manufacturing facilities, working capital and other assets.....	49,898,699	12,031,145

On Jan. 3, 1918, stockholders voted to increase the authorized stock from \$105,000,000 to \$125,000,000, and they have since been given the right to subscribe at par for one share for each ten shares held. On Nov. 24, 1917, directors declared a semi-annual dividend of 2 per cent, payable in stock.

"This action was taken," says Mr. Coffin, "in view of the large surplus from accumulated earnings covering a period of years, invested in manufacturing facilities, working capital and other assets, against which no stock had been issued. Your directors preferred, rather than to increase the rate of cash dividends, to adopt the policy of paying semi-annual stock dividends at the rate of 4 per cent per annum, payable in January and July, in addition to the regular 8 per cent cash dividends."

Total factory floor space in 1917 was 17,573,000 sq. ft., as compared with 15,300,000 sq. ft. in 1916.

Book value of the manufacturing plants on Jan. 31, 1893, was \$3,958,528. In the twenty-four years ended Dec. 31, 1916, additional expenditures of \$88,634,909

were made, and in 1917 \$22,320,895 was added, making an aggregate of \$114,914,332. During the twenty-five years there was written off or carried to "general plant reserve" \$75,975,922, leaving the book value of all plants as of Dec. 31, 1917, at \$38,938,410.

In addition to the \$22,320,895 expended last year it has been necessary to authorize \$13,000,000 for further plant extensions, which will be completed during 1918.

The balance sheet as of Dec. 31, 1917, sets forth manufacturing plant, including land, buildings and machinery, at \$77,028,908, which, less the general plant reserve of \$38,090,498, leaves net \$38,938,410. Real estate, buildings, warehouses, etc., other than manufacturing plants, stood at \$794,210. Stocks, bonds and other securities were listed at \$37,348,608. Cash on hand was \$21,190,675. Current liabilities were \$18,450,025.

Speaking further of the balance-sheet changes, Mr. Coffin says:

For a number of years it has been the practice of the directors to provide against contingencies by setting aside substantial reserves. An examination of these reserves makes it clear that a proportion of them is unlikely to be used for the purpose originally intended, and such proportion, estimated at about \$12,000,000, has therefore been set apart and shown as a general reserve against all assets of the company other than its plant investment.

In past years it has been the company's practice to state its patent account at \$1, but a record has been maintained showing the serial number, date and cost of these patents. That proportion of the cost which represents the unexpired life of the patents, viz., \$3,097,444, is carried as an investment on the company's books, being offset by a reserve of like amount, and both accounts are now shown in full.

Details of the changes in the plant account were:

	Gross Book Value	General Plant Reserve	Net Book Value
Real estate and buildings.....	\$40,533,721	\$15,061,826	\$25,471,895
Machinery	31,274,744	17,808,232	13,466,512
Patents	1,991,110	1,991,109	1
Furniture and fixtures.....	3,229,331	3,229,330	1
Total.....	\$77,028,908	\$38,090,498	\$38,938,410

Give Liberty to the World

LIGHTING QUESTION FROM THE USER'S POINT OF VIEW

Electrical Engineer for Marshall Field & Company, Chicago, Tells of Effect of Light on Volume of Sales of Merchandise and on Factory Production

Frederick J. Pearson, electrical and mechanical engineer for Marshall Field & Company, Chicago, speaking before the Illuminating Engineering Society, Chicago Section, presented facts and conclusions regarding the use of light in the company's retail, wholesale and manufacturing establishments. Light intensity, he said, has a decided bearing on the rapidity with which retail merchandise moves. If time were available, actual data could be prepared from the records of the store to show that increasing the intensity of light beyond what is ordinarily considered a normal value increases the sale of goods in certain departments. The more intense light reacts on customers and salespeople alike. It intensifies the customer's desire to buy and increases the enthusiasm of the sales person. This does not hold true in all departments, however. It would obviously be foolish to try such a plan in the

Oriental goods department. There is, of course, a limit to the intensity that can be used with profit, but this intensity, the speaker thought, will approach daylight intensities more closely as the quality of the light is improved. The better quality of the gas-filled lamps in some measure helps to make possible the present high intensities used in the store. There is much less complaint now from lighting with 7 ft.-candles, 8 ft.-candles and 9 ft.-candles than there was with intensities 50 per cent as great before the advent of gas-filled lamps. Mr. Pearson expressed a firm belief that lighting should be designed for sales efficiency or production efficiency rather than lighting efficiency. He urged a thorough study of the conditions and a design based on the conditions rather than a study of installations already made and a copy of them.

Speaking of factory production in its relation to lighting, Mr. Pearson stated that he had been able to increase factory output as much as 10 per cent by the application of adequate lighting. The intensities used in the factories, of course, depend on the work. The average intensity for general lighting in Marshall Field's plants is from 6 ft.-candles to 7 ft.-candles, with special localized lighting as high as 15 ft.-candles.

The speaker's comment on lighting equipment, given altogether from the viewpoint of the user, was not altogether flattering. He dwelt at considerable length on the inadequacy of showcase lamps and lighting equipment, but stated that it is impossible to do without showcase lighting. He declined to comment on a trial installation which he had made to test many forms of daylight equipment. He expressed the general view that adequate lighting could most easily be secured by a scheme of general illumination supplemented by localized lighting.

How Hydroelectric Energy Saves Coal

Here is a 55,000-kw., 110,000/13,200-volt and 55,000/13,000-volt substation which materially reduces the amount of coal that must be hauled long distances into the great producing centers of the Northwest. It is "Terminal A" of the Minneapolis General Electric Company, which receives at Minneapolis hydroelectric energy from Taylor Falls, 40 miles distant, and from Wisconsin, 90 miles distant. Working at 50 per cent load factor, it will relieve Minneapolis industries from burning 360,000 tons of coal per year.

STUDY OF ECONOMY FOR THE PUBLIC UTILITIES

Addis Whitney of Boston Appointed by Commercial Economy Board of the Council of National Defense

The commercial economy board of the Council of National Defense has arranged with Addis Whitney of Boston to go to Washington in the near future to make a study and a report on opportunities in conservation among the public utilities of the country as a war measure. The board, of which A. W. Shaw of Chicago is chairman, has been instrumental in bringing about various economies in different industries, notably among department stores and laundries, eliminating overlapping deliveries, returning goods sent on approval and in similar ways.

Mr. Whitney has made a preliminary visit to Washington for conferences with officials. It is expected that two or three weeks will be required for his study, which, Mr. Shaw states, will take in possibilities of conservation in the use of capital and material.

He Also Fights Who Buys

DELAY IN WAR FINANCING AFFECTS PUBLIC UTILITIES

Washington Authorities Hear That Need of Prompt Action Is Urgent, but Liberty Loan Campaign Causes Delay

The delay in the organization of the War Finance Corporation, the enabling act for which was recently signed by President Wilson, is, according to reports reaching Washington, seriously affecting a number of large public utilities which have to finance maturities on the first of May. Public utilities in various sections of the country whose officials had looked forward to an early organization of the corporation and had expected that relief in finance would be afforded before this may not be able to obtain the necessary result under the act of Congress until after the present Liberty loan campaign is ended on May 6, when the Secretary of the Treasury will have returned to Washington and be able to take up with the President the subject of organization and appointing directors.

Reports reaching Washington show that between \$15,000,000 and \$20,000,000 in public utility securities will in all likelihood go by default on May 1, when they mature, unless, in the absence of the Secretary of the Treasury, there is assistance from unexpected governmental sources. Newspaper dispatches show that in at least one city, Pittsburgh, a receivership has been applied for, and there are reports in Washington of other possible difficulties.

The conditions, it is stated in Washington, point to the urgent necessity of the speedy organization of the War Finance Corporation, so that the investing public as well as the public utility management may feel that governmental machinery able and willing under proper conditions to come to the relief of the public utility industries has been set up.

There are no indications in Washington yet as to who will be appointed directors in the War Finance Corporation. It is believed that the matter will not be taken up at the White House until the return of Secretary McAdoo from his Liberty loan tour.

Will You Lend for Human Freedom?

WAR SERVICE OF THE WIRE AND CABLE MAKERS

Le Roy Clark Will Act Hereafter as a Government Representative Instead of as Representative of the Manufacturers

At a dinner-meeting of the Wire and Cable Section of the Associated Manufacturers of Electrical Supplies at the Yale Club, New York, on the evening of April 18, the conditions under which co-operation is being developed with the government on war orders were reviewed carefully.

Since the original formation of the wire and cable committee to give the fullest measure of service to the government, several changes have been made, which

LE ROY CLARK

were really in the nature of evolution to meet the necessities of the different government departments as they enlarged from time to time. Thus, the committee became a committee of the General War Service Committee of the Electrical Manufacturing Industry, and as such it represents all of the wire and cable manufacturers, without regard to whether they are or are not association members.

The latest change arises from the fact that Le Roy Clark, president Safety Insulated Wire & Cable Company, who has been the chairman of the wire and cable committee from its inception, has been made a member of the War Industries Board, serving as chief of the wire and cable section of the finished products division.

It was explained at the meeting on April 18 that Mr. Clark, as a result of this appointment, resigns as chairman and as a member of the committee. He, however, will continue to do exactly the same work of allocating government orders, though he will do so now as a government representative instead of as a representative of the manufacturers.

To take the place of Mr. Clark as a member of the

committee, George B. North, Hazard Manufacturing Company, was elected. The committee will elect a chairman later. The organization of the committee will be fully maintained, and it will be used to strengthen the co-operation between the government and the manufacturers.

Everett Morss, president Simplex Wire & Cable Company, a member of the priorities committee of the Council of National Defense, spoke at the meeting of the reorganization of the War Industries Board and emphasized how necessary it is that every manufacturer shall make all of the government work that he can handle in order to meet war necessities as promptly as possible.

A. W. Berresford, Cutler-Hammer Manufacturing Company, recently elected president of the Associated Manufacturers of Electrical Supplies, spoke of the effective work of the Wire and Cable Section for the government.

An interesting report was made by the freight committee.

In connection with the meeting the members of the Wire and Cable Section of the Associated Manufacturers of Electrical Supplies elected officers as follows: chairman, Le Roy Clark; secretary, J. Nelson Shreve, Electric Cable Company; treasurer, Edward Sawyer, Atlantic Insulated Wire & Cable Company.

Back the Bayonets with Bonds

EFFECT OF THE CHANGE TO DAYLIGHT SAVING

William H. Winslow Shows Results of New Plan in Superior, Wis.—Regular Progression of Hour of Sunset

William H. Winslow, vice president and general manager Superior (Wis.) Water, Light & Power Company, has made diagrams showing the results of daylight saving which are reproduced herewith.

One chart shows a comparison of the total station load of that company between 6 and 11 p. m., standard

PROGRESSION AND RETROGRESSION OF SUNSET HOUR

time, or 7 to 12 p. m. as the clocks are now set, for the first week in April, compared with the same days of the week seven days earlier.

It will be noticed that all of the curves except those for Saturday and Sunday show a decrease throughout which is comparatively slight to about 8.30 (9.30 new

time), when it increases quite rapidly. The business of the company is very largely residential, such sales being almost equal to the commercial sales for lighting, and Mr. Winslow attributes the falling off in the load between 6 and 8.30 (old time) to the fact that there is now practically no duplication such as existed prior to April 1, when living-room lights would be turned on

BEFORE AND AFTER DAYLIGHT SAVING

before those in dining rooms, whereas now there is no light required until after the usual hour for the evening meal.

"The reason why the curves for Saturday and Sunday show no falling off until late in the evening and why the total outputs show an increase is that on these days in April we had a severe storm," Mr. Winslow says, "so that it was dark much earlier than usual. Of course, the first Sunday shown on the chart was supposed to be the beginning of the daylight-saving period, but it did not seem to be fully observed, so that I have used it in preference to going back another week."

The other chart brings out the fact, not perhaps generally appreciated, that during the first half of the year the progression of the hour of sunset is much more regular than is its retrogression during the second half of the year. The vertical height of each of the parallelograms shows the difference between the hour of sunset at the beginning and close of the month. It will be noted that the three months of August, September and October show a greater shortening of the days than the lengthening during the four months of February, March, April and May. The hours of sunset used are those given for this altitude in the World Almanac.

"I made this chart in connection with a study of the probable effect of daylight saving," adds Mr. Winslow, "but it is also useful in explaining to customers the rapid increase in their lighting bills during the fall months."

Buy for Liberty—Invest in Bonds

CONFERENCE ON WAR PROBLEMS BY SOUTHWESTERN ASSOCIATION

Rates and Labor Shortage, with High Cost of Operation, Discussed at Meeting at Dallas, Tex. —

W. A. Sullivan Elected President

War conditions were largely responsible for a falling off in attendance at the fourteenth annual convention of the Southwestern Electrical and Gas Association, which closed its session at Galveston, Tex., on April 17. The following officers were elected:

W. A. Sullivan, vice-president and general manager Shreveport Railway Company, president; Burr Martin, general manager Texas Electric Railway, Dallas, first vice-president; E. S. Fletcher, general superintendent Texas Power & Light Company, Dallas, second vice-president; A. Hardgrave, chief operating engineer Southwestern Utilities Company, Dallas, third vice-president, and J. B. Walker, treasurer. H. S. Cooper was elected executive secretary by the newly elected executive committee, making the seventh consecutive time for him to be chosen for this office.

The convention was opened on April 15 with President H. C. Morris, Dallas, presiding. The welcoming address was delivered by Mayor I. H. Kempner and the response by W. B. Head, vice-president Texas Power & Light Company.

Edward F. Harris of Galveston delivered a patriotic address on "War Savings, a Solution of Our National Problem."

Lynton T. Block, president Employers' Indemnity Insurance Association of St. Louis, spoke on "Jovian Insurance."

ADDRESS OF PRESIDENT MORRIS

"Since our last convention so many changes have occurred affecting the public utilities of various kinds comprised within this association that I found it difficult to decide where to begin," said President Morris in his annual address. He continued:

The first and most vital matter is the ratio between operating expenses and gross income, because that ratio must be in favor of the gross earnings to an extent to provide a reasonable return on our investment in our properties or we are potentially bankrupt, for the reason that one of our liabilities is the necessity of continually giving our customers a 100 per cent local service, and we are compelled to cut our service in either quantity or quality.

The most surprising condition which has come upon many of us within the last year is that while our gross receipts have largely increased, our operating expenses have increased in so much greater proportion that in almost every case our profits have decreased. As a matter of law we are compelled to take on under prescribed conditions any new business offered us in normal times, but the times are so abnormal that we are often compelled to protect customers by refusing new business which causes any expenditure for extensions, enlargements or increases.

One of the benefits of this condition is that it has compelled us, and still is compelling us, to investigate thoroughly our ability to saturate more completely the territory covered by our lines.

The ability of the private concerns to raise the prices of their products or services in proportion to the rise in the price of labor and materials used in manufacturing gave them an elasticity in financing which was denied the public utility, whose prices for its product or service were fixed

and which had not the power or the ability to increase them as its operating expenses increased.

The public has never been so educated that it has actually realized that the local utility, with few exceptions, is fully as dependent on ordinary business and commercial laws as is the local flour mill, cotton gin, furniture factory or any other local manufacturing or distributing business.

While present conditions have increased our operation expenses in almost every line and in every department of our business, the two most important things that we have to consider at this moment are labor and fuel. I have put labor first because all the rest of our business is dependent on it. Labor is the personal, human element which, when everything is fully reckoned up, makes us or mars us. We can accumulate a surplus of fuel, we can use a less economical or less efficient fuel, but we can do neither without labor. Under the peculiar conditions now confronting us, the "labor market" is so depleted that we cannot get the desired number of laborers. We not only have to make the best of what we have, but the prospects are that even this "best" may be further depleted in the near future. We have the experience of England and France to guide us, and this experience of theirs has shown only two methods of meeting the emergency. One of these is using a different character or class of labor from any ever used before. The other is making the present labor more efficient by supplementing it with labor-saving machinery. It is probable that we may have to do both.

With the proper and increasing objection to child labor, there is left as the single alternative the use of woman labor. England and France are not alone in the use of woman labor. Our own East and Middle West are employing women in work which twelve months ago would have been given to men only. We of the South and Southwest have certain traditions with respect to the employment of women in positions necessitating hard manual labor of great publicity which will make it difficult immediately to follow the example set in other portions of the country; but we may soon be compelled to follow their example.

We of the utility business are behind other manufacturing and distributing plants in the use of labor-saving machinery. With the sole exception of firing our boilers we have been plodding along with the same proportion of labor to our output as we have for years past. It is true that we have greatly increased the size of our generating, transmitting and distributing units, and have thus indirectly decreased the proportion of labor to output. That has been in most cases a resultant not fully considered in the investment, because the reason has been to obtain greater efficiency and economy in our apparatus. If by the expenditure of \$500 we make a net saving of only 10 cents per day in labor we have made an annual saving of \$36.50 per year, which is over 7¼ per cent on the investment. This is almost as good as a Liberty bond and nearly as patriotic, for we have released nearly \$40 worth of actually useless labor, and as badly as the government needs labor at this time every cent's worth wasted is a crime.

The question of fuel in Texas is a complicated matter, because we have four fuels locally available, coal, lignite, natural gas and oil. The distances in the State are so great that freight and pipe lines costs are a large factor. The necessities of the national government are such at this time that not only have the mine prices been raised on coal but freight rates in some cases have also been advanced. It seems probable that the use of oil as fuel may be still further restricted in the future to an extent which will make it too costly or too uncertain for the use of public utilities.

There has come at least one bright spot in the gloom surrounding the public utilities at this time, and that is the recognition which they have received at the hands of the government. No one can read the letters of our President and our Secretary of the Treasury or the reports of the Comptroller of the Currency and feel that our efforts have not been fully appreciated.

At the second day's session reports were made by H. S. Cooper, secretary of the executive committee.

Discussions on "What Are Many of Us Going to Be Compelled to Do on the Fuel Question?" and "A Safe

Method of Public Procedure When Increasing Operating Expense Necessitates Increase of Rates" filled the morning session on April 16. These were followed by a discussion on the possibility of using lignite for fuel. Fuel questions were brought up again at the afternoon session.

STUDY OF LIGNITE PROPOSED

Secretary Cooper displayed a geological map of Texas, in which locations of lignite beds were shown. These were found to be near the largest public utility plants. Mr. Cooper said that the deposits would be useless unless steps were taken to make the fuel easier to handle. He said that North Dakota has spent considerable money in looking into the possibilities of its lignite operations and that lignite is being stored in that State.

It was decided to consider sending two young men to the University of Texas to take a special course in geology for the purpose of endeavoring to find a solution for the fuel problem through lignite beds. H. C. Morris, Dallas, said that students of the University of Michigan and Cornell University are now studying the lignite problem with the hope that they may find a way in which the product may be used for fuel. These students are receiving geological instruction at the expense of public utility concerns.

The question of increasing rates was discussed by nearly every one in attendance. The prevailing opinion was that eventually rates must be raised because of the increased costs of labor and fuel. J. C. Kennedy of Brenham reported that some concerns have increased their rates without receiving complaints from the public.

Others maintained that in nearly every instance the public probably would complain if rates are increased, but that the public must be educated to the fact that it may be necessary to increase the rates on account of conditions being abnormal. Several expressed confidence that the public would not complain if reasonable increases in rates are made, and all delegates declared that no excessive profits should be made during the war. Every delegate declared that his company is endeavoring to give the best service possible and that consumers in general are pleased with the service.

A. Hardgrave, Dallas, said that no company should expect to increase rates except in cases of necessity. Several said that the companies should take up the matter of increasing rates with the city officials before making increases. Fred P. Brien, Amarillo, said that each company should have its employees become familiar with conditions and that by working out this plan the employees would tell the public of the conditions.

Secretary Cooper said that in any event the rates should be made equitable. "It may not be so much a matter of increasing rates as it may be of revising rates," he declared.

The question of obtaining sufficient labor during the war also was discussed. Delegates said that they were making the best of conditions under the circumstances, but all of the companies have lost considerable numbers of capable employees on account of the draft. Some companies are training men who are not subject to draft.

R. W. Van Valkenburgh, Dallas, general manager of

the Texas Western Electric Company of Texas, read a paper on "Suggestions for Conservation in Purchasing from the Seller's Standpoint." The paper contained numerous suggestions that might be used by the sellers and pointed out the necessity of conservation. The paper was followed by discussions on the subject.

Build for the Future—Buy Bonds

COMMISSIONS SHOULD HAVE POWER TO INCREASE RATES

Commissioner Whitney of New York Says that
Policy Must Assure Development and
Improvement at All Times

Commissioner Travis H. Whitney of the New York Public Service Commission, First District, describes the attitude of the commission as a recognition of the need for a close continuous scrutiny of the public utility corporations and for a rate that will "yield operating expenses, depreciation and obsolescence and a moderate return on the actual value of the property." This appears in a statement prepared by Mr. Whitney concerning the commission's administrative, judicial and legislative functions.

It is stated that when operating expenses are lowered through a decline in wages, costs or otherwise there is reason for reducing the rates charged the public, but when the reverse condition prevails the commission should have the power to increase rates.

Commissioner Whitney says further:

The commission must see that the public gets what it pays for. That task requires the constant supervision of all phases of public utility service. The basis of the right of a public utility to charge a reasonable rate and earn a reasonable return is the furnishing of adequate service, and the duty of the commission is to determine what service shall be rendered and the rate to be paid for that service.

The commission must see to it that the public pays for what it gets. The commission ought to be at all times in a position to see to it that the rates are such as to represent payment by the public for what it gets, no less and no more. If the company is to be at all times denied the right to earn more than a fair return when operating costs are falling, it cannot be left to earn less when costs are mounting.

The commission must see to it that the policy pursued by it and by other public authorities is such as to assure at all times the development and improvement of public utility enterprises. It must also see that the conditions surrounding public utilities are such as to encourage new utilities where and when needed, and generally to attract the necessary capital to enable the upkeep of the properties and service at suitable efficiency.

Capital can be drawn to public utilities from private enterprises only by establishing an attractive relationship between the certainty of return and the percentage of return the utility is allowed to earn upon the money of investors.

It is also shown by Mr. Whitney that if capital is deterred from embarking in public utility enterprises the public suffers.

The Legislature will be asked to amend the public service commissions law so that the commissions will have authority to raise rates as well as to reduce them.

End the Spy System—Buy Bonds

Associations and Societies

A complete Directory of Electrical Associations is printed in the first issue of each month on the next-to-last text page.

Synchronous Club of Los Angeles.—The annual banquet of this club was held in Los Angeles on April 18.

A. S. M. E., Providence Section.—The power division of the Providence Section of the American Society of Mechanical Engineers will hold a discussion on "Thermal-Insulation Covering" on May 9.

A. I. E. E., Madison Section.—On April 16 G. E. Wagner talked on "Three-Phase, Four-Wire Distribution" before the Madison (Wis.) Section of the American Institute of Electrical Engineers.

A. S. M. E., Los Angeles Section.—"Power Sources and Distribution in California" will be discussed at the meeting of the Los Angeles Section of the American Society of Mechanical Engineers in May.

New York Electrical Credit Association.—On Tuesday evening, April 30, the New York Electrical Credit Association will hold its regular annual meeting at the Building Trades Club, 30 West Thirty-third Street, New York.

A. I. E. E., Cleveland Section.—"Storage Batteries in War" was the subject of a talk delivered by M. R. Berry, president Electric Products Company, before the Cleveland Section of the American Institute of Electrical Engineers on April 22.

Electrical League of Cleveland.—Major Ross C. Cockburn of Toronto, Canada, a veteran of Canada's Expeditionary Forces, gave an interesting address entitled "The First Canadian Contingent" before the Electrical League of Cleveland on April 18.

A. I. E. E., Seattle Section.—F. Lindsay presented a paper on "Recent Additions to the Generating Equipment of the Puget Sound Traction, Light & Power Company" on April 16 before the Seattle Section of the American Institute of Electrical Engineers.

A. I. and S. E. E. Inter-Section Meeting.—The Pittsburgh and Cleveland Sections of the Association of Iron and Steel Electrical Engineers will hold a joint session at Youngstown, Ohio, on May 18. A special trip will be made to the McDonald and Ohio works of the Carnegie Steel Company.

A. I. and S. E. E., Philadelphia Section.—On May 4 the Philadelphia Section of the Association of Iron and Steel Electrical Engineers will hold a meeting at the Majestic Hotel, at which H. A. Lewis and W. H. Burr will present a paper on "Electrically Operated Door Hoists for Open Hearths and Furnaces." Major William A. Garret will address the meeting on "Some of My Observations in France."

Western Society of Engineers.—"Storage of Bituminous Coal" was the topic of a paper read by H. H. Stoeck, professor of mining engineering, University of Illinois, before the Western Society of Engineers at Chicago, April 15.

A. I. and S. E. E. Section Meeting.—T. F. Bailly, president of the Electric Furnace Company, is to read a paper on "Electric Soaking Pits, Annealing and Heat-Treating Furnaces and Furnaces for Melting Non-Ferrous Metals" before the Cleveland Section of the Association of Iron and Steel Electrical Engineers on April 27.

A. S. M. E., New York Section.—"Labor Turnover" will be the subject of a discussion at the May 21 meeting of the New York Section of the American Society of Mechanical Engineers. The subject will be presented by Captain Boyd Fisher of the War Industries Board at Washington and G. R. Woods of the Allied Machinery Company.

Electric Club-Jovian League.—The Electric Club-Jovian League of Chicago has recently listened to two war addresses. Rufus C. Dawes gave some amazing figures on the cost of the war and on the sums of money expended by the United States. Alexander Reichmann spoke on April 18 on "Reflections on the War, Its Consequences and Problems."

A. I. E. E., Schenectady Section.—"Modern Transformers" was the subject of an illustrated address delivered by J. J. Franks of the engineering department of the General Electric Company before the Schenectady Section of the American Institute of Electrical Engineers on April 19. The design of both large and small transformers was discussed.

Jovian League, Atlanta, Ga.—A chapter of the Jovian League has been formed in Atlanta that will include Jovian and non-Jovian members. It will be made up strictly of those in the electrical industry. The membership will be limited to fifty during the first six or eight months, and the object will be of a promotional character both for electrical and civil purposes. C. D. Cabiness, Western Electric Company, has been chosen as the first president, and C. A. Collier, Georgia Railway & Power Company, secretary-treasurer.

Ohio Electric Light Association, New-Business Meeting.—The industrial power and heating section of the new-business committee of the Ohio Electric Light Association will hold a meeting at the Electrical League club-rooms, Statler Hotel, Cleveland, on May 8. Papers to be presented are: "Present Status of the Electric Brass Furnace," by H. M. St. John, research engineer, Commonwealth Edison Company, with discussion by E. F. Collins, Schenectady, N. Y., and T. F. Bailey, Electric Furnace Company, Alliance, Ohio; "Silent Chain Drives Used in the Application of Electric Motors," by Paul V. Wheeler, Cleveland; "War-Time Economies," by W. A. Wolls, Columbus Railway, Light & Power Company, Columbus, Ohio.

Recent Court Decisions

Findings of higher courts in legal cases involving electric light, power and other public utility companies.

Liability for Injury on Private Premises.—Where plaintiff's injuries resulted from electric wires of defendant city left lying on private premises, the city's liability depends on whether plaintiff was a trespasser or had a legal right to be on the premises, according to the Court of Appeals of Kentucky (200 S. W. 931).

Condemnation Denied Where Acquisition Will Not Accomplish Object.—Where another company has condemned part of land intended by a water company to be a part of its project, proceedings by the latter to condemn the remaining part will be dismissed where the acquisition of such lands could not accomplish its object, as shown by its filed maps and plans, the Supreme Court of New York held in Ramapo Mountains Water Power & Service Company vs. Seidler (168 N. Y. S. 737).

Contract to Furnish Energy.—Where complainant had paid for electric light to be furnished for three years pursuant to a contract an injunction will issue to prevent cutting off the light or to compel a public utility company which had turned the current off to turn it on again, the Supreme Court of Arkansas held (200 S. W. 799). A contract by an electric company to furnish a consumer free energy for three years upon being released from a previous contract to furnish energy for a share of the consumer's earnings was held not invalid because discriminatory in a case where the franchise from the city did not appear to prohibit such contracts.

Franchises Free from State Control.—While the state may authorize municipalities to grant a franchise to a public service corporation free from the exercise of the state's power of regulation, such franchises are never construed to have that effect unless the state's grant of authority and the municipality's grant in the franchise are clear and positive, according to the Supreme Court of Indiana (118 N. E. 531). A state may ratify a franchise granted by a municipality which excepts the grantee of the franchise from the exercise of the state's power of regulation, even though the municipality had no authority so to exempt at the time of granting the franchise. The act of 1867, as amended in 1891, giving the common council of a city exclusive power over the streets, highways, alleys and bridges within the city did not authorize the city to grant a franchise to a public service corporation free from the state's police power to regulate.

Current News and Notes

Timely items on electrical happenings throughout the world, together with brief notes of general interest.

Fuel Administration and Utility Ownership Problems.—A letter from Dr. H. A. Garfield, the federal Fuel Administrator, has been made public by representatives of the United Improvement Association of Los Angeles, Cal. That association sent recently to the federal Fuel Administration a copy of a letter in which the association urged the city council of Los Angeles to take action to conserve the city's power rights. "You may rest assured," says Administrator Garfield, "that the Fuel Administration will do nothing under the guise of conservation that would cause injustice to the people of Los Angeles, and that the State of California must determine for itself whether municipal ownership or private control shall be the future policy in its regulation of public utilities."

Electric Storage Battery Earnings.—The annual statement of the Electric Storage Battery Company, Philadelphia, for the year ended Dec. 31, 1917, shows gross sales, less cost of manufacture and purchases and all expenses incident thereto, amounting to \$3,140,560. Operating expenses, including salaries, commissions, engineering, selling and traveling expenses and rent of branch offices, were \$919,947. Net earnings from sales were \$2,220,613. Other income amounted to \$257,269, making total net earnings of \$2,477,882. There was reserved for 1917 federal taxes \$450,000, leaving a balance for surplus account of \$2,027,882. The balance of Dec. 31, 1916, amounted to \$2,318,686. Dividends paid during 1917 aggregated \$649,967, and "sundry adjustments of accounts and all items not incident to the current year" aggregated \$102,009. The net surplus was \$3,594,592.

School for Women Substation Operators.—Because of the existing and constantly increasing shortage of male labor due to war conditions, the generating department of the Edison Electric Illuminating Company of Boston has started a school for women substation operators. The school opened March 25 with fifteen members at the service buildings, and is being conducted by the laboratory, under the direction of P. J. Kent, system operator of the generating department. The school for women operators has been started as an experiment, to determine whether it is practicable, as a war measure, to substitute them for men in some substations. The women are receiving the same pay at this school that the men are receiving at the L Street school. Married men and men over the draft age will not be displaced by women, but only young single men of small experience.

Effect of Closing Window-Glass Factories.—With the first operating period allowed manufacturers of window glass by the United States Fuel Administration at an end, and the closing of approximately forty-five such plants, largely distributed through Pennsylvania, Ohio and West Virginia, a statement made public by John R. Johnston, secretary of the National Association of Window Glass Manufacturers, shows that the early closing order has resulted in a great saving of fuel, labor and freight capacity. The curtailment of output in the window-glass trade, according to the statement of Secretary Johnston, will save 450,000 tons of coal and 18,000 freight cars and release 5500 workmen for other labor. The direct loss to glass blowers, the statement says, will approximate \$3,000,000, although this will be reduced by earnings in other industries. The resulting shortage in window glass is estimated at 5,500,000 boxes, or about half the yearly output of 11,000,000 boxes.

Opportunities in the Ordnance Department.—Two statistical engineers are needed by the Control Bureau, Ordnance Department, Washington. Each position calls for a man who is keen, an analyst, with vision, accomplished in the compilation of reports and statistics, and able to put himself in the reader's place. He should be a college or technical graduate and from thirty-five to fifty years of age. There is also an opportunity for two men along the same line but with less experience and younger. Four men are also wanted experienced in cost keeping and bookkeeping who have skill and initiative. They must be over the draft age. There is an opportunity here for men with and without college degrees. Women college graduates with mathematical ability and actual practical experience in such work as bookkeeping and statistics and able to make charts of various kinds are also desired. Address Chief of Personnel of Control Bureau, Chief of Ordnance Department, Washington, D. C.

Stevens Institute for Steam Engineering Training School.—The Navy Department, after consultation with President Humphreys, has designated the Stevens Institute of Technology, Hoboken, N. J., as the headquarters for the new United States Naval Steam Engineering School for the training of engineer officers for the United States Naval Auxiliary Reserve. This school is the only one devoted to training engineer officers for steam-engine service and is a branch of the large training school at Pelham Bay Park, New York. There is at Pelham, in addition to the school for general training of enlisted men, an officers' material school, Naval Auxiliary Reserve. Both the school at Pelham and the engineer officer school at Stevens are under the supervision of the supervisor of the Naval Auxiliary Reserve. The education of the engineer officers at Stevens is directed by Prof. F. L. Pryor of that college, who has been appointed by the Navy Department, with the approval of President Humphreys, civilian director.

Commission Rulings

Important decisions of various state bodies involving or affecting electric light and power utilities.

Contracts in Illinois.—In an issue affecting the Normandie Hotel Company and the Commonwealth Edison Company, Chicago, the Illinois Public Utilities Commission says in part: "It appears that the consumer in signing a contract in August, 1916, signed it with a different name from that signed to the original contract. Knowledge that the café and hotel were operated under one management could only have been obtained through an inquiry into the business affairs of the consumer. Such an inquiry could hardly have been expected of the Commonwealth Edison Company and might have proved a source of embarrassment to the consumer. In case the company, acting in good faith, accepts a signature to an application for service, the commission believes that a practice requiring inquiry into the ownership of the business would result in imposing unwarranted expense upon the company and would further result in just complaint and criticism on the part of the consumer. The commission therefore finds that under conditions existing at the time of signing the contract, in August, 1916, the company was under no obligation to inquire into the ownership and management of these premises. A further question exists as to whether the company, after determining that an error has been made in signing the contract as hereinabove set forth, should be ordered to refund to the consumer the difference of bills which has resulted from this error. To impose this obligation upon the company would result in opening innumerable contentions for refunds, many of which might have a semblance of justice and many of which would be unjust, but all of which would involve an adjudication of issues which had arisen during times long since past. The adjudication of these issues, if conducted properly, would involve a large amount of investigation and expense. The liability of the company for the errors which it has committed, due to wrongful meter readings or discrepancies in billing, cannot be denied, but to extend this liability to cases which involve errors on the part of the consumer would offer problems of an entirely different character. Quite aside from any legal obligation and liability which the company may have in this or similar cases, and upon which the commission is not passing, to hold in this case that the reasonable practices of the utility warrant a refund of the overcharges would be in effect holding that the company is liable not only for its own errors but for the errors of its consumers. The commission believes that this would be unreasonable."

Charles H. Session has been appointed a member of the Kansas Public Utilities Commission.

R. T. Carruthers has been appointed district agent for the Southern California Edison Company in the Visalia district.

R. H. Ballard, second vice-president and assistant general manager of the Southern California Edison Company, in the rearrangement of titles becomes first vice-president.

Charles Strong has resigned as engineer for the Galva (Ill.) Electric Light Company to become connected with the Galesburg & Kewanee (Ill.) Electric Railway Company.

O. E. Hines, formerly new-business manager of the Washington (Ohio) Gas & Electric Company, will succeed C. B. Owens as manager of the Boonville (Mo.) Light, Heat & Power Company.

Harry Strapp, a load dispatcher for the Edison Electric Illuminating Company of Boston, Mass., has resigned to become superintendent of the Towns Electric Light Company, Harbor Grace, Newfoundland.

Jerome L. Cheney of Syracuse, N. Y., has been appointed a member of the Public Service Commission for the Second District of New York State, to fill the vacancy caused by the death of William Temple Emmet.

C. W. Beck, formerly superintendent of the Valparaiso (Ind.) Lighting Company, has been appointed manager of the Albion (Mich.) Lighting Company. Mr. Beck was graduated from the University of Nebraska in 1914.

Albert M. Grall, Webb City (Mo.) representative of the new-business department of the Empire District Electric Company, has been made new-business manager of the Ashland (Ohio) Gas & Electric Company.

George H. S. Mart, for the last seven years superintendent and commercial manager of the Knoxville (Tenn.) Railway & Light Company, has opened an office as a consulting and efficiency engineer in the Holston National Bank Building, Knoxville.

H. A. P. Langstaff, for the past two years associated with Willis L. Adams as electrical engineer, has resigned to become field electrical engineer for the J. G. White Engineering Corporation at Muscogee Shoals, Ala., on the United States government nitrate plant No. 2.

Harry L. Thomson has been promoted from assistant superintendent of lighting of the Hartford (Conn.) Electric Company to superintendent of lighting, succeeding F. W. Prince. Mr. Thomson, who is a graduate of the Rensselaer Polytechnic Institute, has been connected with the Hartford company since 1910.

Arthur L. Mullergren, secretary-treasurer of the Benham Engineering Company, consulting engineers, Oklahoma City, Okla., has been commissioned a first lieutenant in the Quartermaster's Corps of the National Army and assigned for duty as officer in charge of light, power and ice, camp utilities division, Camp Funston, Kan.

Men of the Industry

Changes in Personnel
and Position—
Biographical Notes

J. R. Newell, formerly in charge of electrical construction, has been appointed superintendent of electrical operation for the British Columbia Electric Company, succeeding W. H. Fraser.

W. H. Fraser, superintendent of electrical operation for the British Columbia Company of Vancouver, B. C., has resigned that position to undertake similar work for the Mexican Light & Power Company at the city of Mexico.

Arthur Preger has been promoted by the Federal Light & Traction Company from the assistant treasurership of the Springfield (Mo.) Railway & Light Company and the Springfield Traction Company to be manager of the Albuquerque (N. M.) Electric Light & Power Company, succeeding W. P. Southard.

George Steinwedell, a former member of the new-business department of the Denver Gas & Electric Company, has been made manager of the Binghamton (N. Y.) Gas & Electric Company. On leaving Denver Mr. Steinwedell became advertising manager for the St. Paul Gas & Electric Company and then went East.

P. M. Downing, chief engineer of the electric department of the Pacific Gas & Electric Company, San Francisco, Cal., has been placed in charge of the combined operating plants of the Pacific Gas & Electric Company, Great Western Power Company and Sierra & San Francisco Power Company, which have pooled their activities as a means of aiding in the general conservation of fuel oil.

Prof. Philip B. Woodworth, dean of electrical engineering of Lewis Institute, Chicago, has entered the government service as a major in the aviation section of the Signal Corps. Professor Woodworth in 1910 became associated with the patent law firm of Rummler & Rummler, Chicago, where he gave his attention to applications for patents on electrical products and patent suits involving electrical points.

F. T. Morrissey, who has been associated with the Southern Illinois Light & Power Company and its subsidiary, the Saline Electric Company, for several years past as manager of its Duquoin (Ill.) properties and is at present district manager of its Eldorado group of properties, has resigned to become associated with the Indiana Railways & Light Company at Kokomo, Ind. Mr. Morrissey was previously connected with the Illinois Northern Utilities Company, the Kansas City Electric Light Company and the Eastern Michigan Edison Company.

C. B. Owens has resigned as manager of the Boonville (Mo.) Light, Heat & Power Company to enlist in the Thirty-seventh Engineers.

C. W. Squier has resigned as assistant electrical engineer of the Public Service Commission for the First District of New York to become a member of the editorial staff of the *Electric Railway Journal*.

Charles Philip Coleman has advanced in position from vice-president to president of the Worthington Pump & Machinery Corporation. Prior to becoming vice-president of the corporation, in May, 1916, he was receiver of the International Steam Pump Company, an associate company. Mr. Coleman, who is a graduate mechanical engineer of Lehigh University, has had considerable experience in industrial and railroad corporations. He joined the International Steam Pump Company in 1913 as vice-president, and upon the outbreak of the war in 1914 was made one of the co-receivers of the company, becoming sole receiver in 1915.

W. B. Voth has resigned as manager of the Ogdensburg (N. Y.) Street Railway, the Ogdensburg Power & Light Company and the Ogdensburg Gas Company to become manager of the properties at Eau Claire, Wis., operated by the Wisconsin-Minnesota Light & Power Company. Mr. Voth is a native of Milwaukee. He was graduated from the University of Wisconsin in 1897. After designing, constructing and operating several small hydroelectric plants in his native State, he was appointed resident engineer at Sheboygan in 1904 during the building of a steam station and the reconstruction of the local commercial and street-lighting system. After finishing the construction work, Mr. Voth remained to operate the plant as general superintendent. At the same time he acted as consulting engineer for the Greensboro (N. C.) company, controlled by the same interests. He resigned from these companies in 1914 to enter the service of the Empire United Railways.

C. R. Dooley, manager of the educational department of the Westinghouse Electric & Manufacturing Company, has been granted a leave of absence to enable him to accept an appointment by the government as director of the vocational educational project for army needs, now being developed by the War Department committee on educational and special training. He will be in the War Department at Washington. With the assembling of the first drafted men at Camp Sherman, Mr. Dooley was given the task of instituting and putting into operation a system of classification by which it is possible in a few minutes to select from the men in the cantonment the one best fitted for any particular class of service. The efficient manner in which this system was installed is largely responsible for Mr. Dooley's second call from the government. During Mr. Dooley's absence from the Westinghouse company his duties there will be assumed by C. S. Coler, who has been appointed acting manager of the educational department.

Louis H. Mather has been appointed superintendent of distribution for the gas and electrical department of the city of Norwich, Conn.

F. A. C. Tocque, formerly new-business manager of the Fort Smith (Ark.) Light & Traction Company, has passed the necessary examinations for entrance into the Canadian officers' training camp and will sail for England.

Fred M. Reast has resigned from the engineering inspection branch of the Western Electric Company to become second lieutenant in the Quartermaster's Corps of the National Army and is now stationed at Camp Holabird, Baltimore, Md.

Ainslie A. Gray of the firm of Gray & Benjamin, advertising specialists, Chicago, has been commissioned major in the Ordnance Reserve Corps and will have charge of a new publicity bureau that will endeavor to co-ordinate the activities of the Ordnance Department and the industries through the medium of the technical and trade press. Formerly he was vice-president and general manager of the Electrical Review Publishing Company. He joined the staff of the *Electrical Review* in 1902, becoming managing editor in 1905. When the Electrical Review Publishing Company purchased the *Western Electrician* he became managing editor of the consolidated paper. In 1909 he also became general manager of the company and in 1914 was elected vice-president. He was made vice-president of the Chicago Trade Press Association in 1913 and the following year became its president. In 1915 he was elected president of the Federation of Trade Press Associations. In 1916 this body was reorganized as the Associated Business Papers, Inc., and Major Gray continued as its president until last year.

J. W. Welsh, electrical engineer and traffic agent of the Pittsburgh (Pa.) Railways, has been called to Washington, D. C., by A. Merritt Taylor, manager of passenger transportation of the Emergency Fleet Corporation of the United States Shipping Board. Mr. Welsh, who will serve on Mr. Taylor's staff, will assist in providing transportation facilities and remedying deficiencies, where such exist, in the shipyards on the Atlantic and Pacific coasts. Mr. Welsh became associated with the Pittsburgh Railways in 1906 as assistant electrician. In 1910 he was made electrical engineer and in 1913 took charge of the traffic department. Prior to this time he was employed as an electrical engineer by the National Tube Company, Wheeling, W. Va., and also by the Westinghouse Electric & Manufacturing Company at East Pittsburgh. He was graduated from Wittenberg College in 1900, Harvard University in 1901 and the Massachusetts Institute of Technology in 1903. He is a fellow in the American Institute of Electrical Engineers and several years ago served as chairman of the Pittsburgh Section of this organization. Since 1914 he has been chairman of the power generation committee of the American Electric Railway Association.

J. S. Wharton, formerly manager of the Southern Gas & Improvement Company at Henderson, N. C., and having charge of the gas plants at Elizabeth City, N. C., and Rock Hill, S. C., has been appointed manager of the Helena (Ark.) Gas & Electric Company.

William H. Merrill, president of the Underwriters' Laboratories, Chicago, has been appointed section committee chairman of the newly organized fire prevention section of the War Industries Board of the Council of National Defense. Mr. Merrill is now in Washington to assume the duties of the new position for the period of the war. He brings to the fire prevention section experience in fire prevention engineering gained during a period of twenty-five years of active participation in nation-wide fire-prevention work. Four years after his graduation from the Massachusetts Institute of Technology, in 1889, he went to Chicago as elec-

W. H. MERRILL

trician with the Chicago Underwriters' Association, and in the following year, upon association with the Western Insurance Union, organized the Underwriters' Bureau of Fire Protection Engineering. Mr. Merrill assisted in the organization of the electrical committee of the old Underwriters' National Electric Association, and participated in the conferences which resulted in the National Electrical Code. He was secretary-treasurer of the National Fire Protection Association and president two years, besides being for a long time a member of its executive committee and other important committees interested in the maintenance of electrical standards.

Obituary

James A. Scrymser, president of the Central and South American Cable Company and the Mexican Telegraph Company, died at his home in New York City on April 21, in his seventy-ninth year. Mr. Scrymser was a pioneer in the establishment of wire communication between the United States and Latin America, and in 1917 succeeded in establishing the first American-owned line direct between the United States and Brazil.

Charles H. Merritt, general manager of the Danbury (Conn.) & Bethel Gas & Electric Light Company, died April 3 in his seventy-fifth year. Mr. Merritt went to Danbury in 1868 and entered the shoe business, in which he continued until 1880, when he became interested in the hat trade, in which he remained until his retirement in 1907. Before 1880, however, Mr. Merritt had become a public utility figure in Danbury, he having been connected with the old gas company and later with the electric company, becoming president and general manager while still in the hat business. When the Doherty interests took over the Danbury company in 1912 Mr. Merritt headed it, and he has remained in that position ever since. Mr. Merritt's local activities extended far beyond business, however, and he was very active in charitable and social work.

Dr. Ferdinand Braun, who in 1910 shared with William Marconi the Nobel prize for physics awarded for services to humanity through the invention of improved methods in wireless telegraphy, died in New York City on April 20 in his sixty-ninth year. Dr. Braun was born at Fulda on June 6, 1850, and received his education at the universities of Marburg and Berlin, graduating from the latter in 1872. In 1895 he was appointed director of physics at the University of Strassburg. He came to this country in 1915 as a witness in the litigation between the Marconi company and the German company which operated the wireless plant at Sayville, Long Island, and Tuckerton, N. J. His early studies were devoted largely to mechanical oscillations, but later he devoted his attention chiefly to research on electrical problems, and more particularly to radio-telegraphy.

James P. Merrihew, one of the oldest of the telegraph and telephone engineers, has recently died at the age of eighty. He started his career as a messenger boy with the Western Union and at the age of sixteen was manager of a telegraph office in a small New Jersey town. About 1877 Mr. Merrihew and the late W. T. Westbrook, Sr., secured a license from the American Speaking Telephone Company and established exchanges at Wilmington, Chester and Trenton, under the firm name of J. P. Merrihew & Company. On July 18, 1882, the Delaware & Atlantic Telephone & Telegraph Company was organized by Mr. Merrihew at New York, and a few months later a similarly named company was incorporated under the laws of the State of Pennsylvania. He was the first president and also a member of the board of directors and remained at the head of these conferences until July, 1897. For a number of years he was president of the Bell Telephone Company of Philadelphia. In the early seventies he was manager of the Western Union force in Philadelphia and later became superintendent of the sixth district. About the year 1880 he became the general superintendent of the Western Union company.

TRADE & MARKET CONDITIONS

News of the Trade for the Manufacturer, Wholesaler and Jobber
of Electrical Equipment and Supplies—
Notes on Industrial Activities and Business Methods

DEMAND FOR TRANSFORMERS HAS DROPPED CONSIDERABLY

Shipments Can Now Be Made Under Six Months on
All Sizes and Types—Stock on Smaller Sizes Is
Being Accumulated

Since early last fall transformer business has dropped from the high level occasioned by the entry of the United States into the war. Present-day demand is probably in the neighborhood of 70 per cent of what it was ten months to a year ago. During the past few weeks the demand has been noticed to rise somewhat, and indications are for a continuance of the present volume of business.

While it is true that the manufacturers have by no means entirely caught up with old business, deliveries are now much closer to normal. In some sizes and types stocks are beginning to accumulate. Present manufacturing capacity is now in excess of current demand.

Shipments on all sizes, even for special construction, are now being made well under six months. Under 50 kva. shipment in four weeks is being promised, and in many cases orders are being filled from stock. Longer time is required for larger sizes, but only recently some very large transformers were ready for shipment in four months.

There does not seem to be any tendency toward lower prices, while there is some talk by manufacturers of higher prices if raw materials continue to advance. Present contracts, of course, will not be affected, but new contracts may be made on a different schedule or price basis. Boiler plate and cotton thread are at present the most alarming of the raw materials. Transformer oil deliveries are now in better condition, and the supply of oil drums is freer.

Obeys That Impulse—Buy a Bond

RETURN-GOODS NUISANCE SUPPRESSED BY JOBBERS

Dealers or Contractors Must Obtain Permission
Before Credit Is Allowed—Rigorous Rule
to Bring This About Is Applied

Returning merchandise to the jobber, distributor or manufacturer by the dealer or contractor, at their own discretion, and demanding credit allowance in addition, without first obtaining permission, has been greatly abused. In fact, to accept the statement of a number of jobbing houses, the practice had actually become a menace, so widely was the custom followed. Other lines of business have been victimized in the same way by unscrupulous buyers, so much so that organized efforts to lessen the evil, if not wholly suppress it, have received special attention at the hands of trade associations. It is generally admitted, however, that keen competition for orders is alone responsible for these and similar loose business methods. Conditions since the advent of the war have changed radically.

Jobbers may differ in their ways of handling the return-goods problem, but after inquiry it is ascertained that concerns of standing have a rule in connection therewith which they enforce. The following, appearing in a recent price list of a prominent jobber, is a fair sample of them all:

"No goods can be returned for credit without our permission, first obtaining our return-goods tag, to be attached to goods returned. All goods returned for credit must be in salable condition, and all charges must be prepaid. A

minimum service charge of 20 per cent will be made on all standard apparatus returned for credit. No permission will be given to return apparatus of any special finish, design or capacity. No permission will be given to return apparatus that has been shipped over sixty days."

Every Bond Brings Victory Nearer

TEMPERAMENTAL WORKMEN AT WIRE PLANTS TROUBLESOME

Skilled Operatives Have Peculiarities as Specialists
and Have a Tendency to Be Shifting
All the Time

Besides the difficulty of obtaining early or prompt delivery of copper to the wire drawers and manufacturers, labor at these plants is not only short but at times creates embarrassing conditions. One large wire producer said the major part of the labor force were foreigners—Poles in many instances. They are skilled men, excellent artisans, but inclined to be "temperamental." The practice at this and other plants is to use the working operatives to the best advantage.

Occasionally the supply of bare copper wire runs low, and replenishment cannot always be accomplished now readily and promptly. At such periods the management shifts these men to other departments and on different tasks. This is resented. The workers prefer to follow one particular line in which they are proficient and skilled. Consequently when a shift is made to conserve time and material these workmen not infrequently "throw up" their jobs and leave for other wire plants where perhaps their specialty may be followed. The absence is usually brief, for the same procedure brings the easily ruffled workman back to his original place of employment and temporary contentment. It is said that there is continually a round of changes on this account. While this break in the plant's working personnel is a source of annoyance, the frequent holidays—mostly of a religious character—also upset the smooth running of the factory and cut down the output. One day is not sufficient to attend to these duties, but two are usually the rule and not the exception.

Let Your Gold Eagles Rout the Hun

FAN PRODUCTION MAY FALL SHORT OF REQUIREMENTS

Government Needs, Running Into Great Quantities,
Largely Overlooked—Difficulty Met in
Obtaining Transportation

An investigation seems to prove conclusively that electric fans will be in none too plentiful supply by the time the retail selling season arrives. Several manufacturers admit the possibility of a shortage at the present time. Inquiries for additional stocks are already coming in. No one, it is averred, foresaw the enormous governmental requirements for military and naval needs at the camps, aboard ships, at hospital bases, and for various other purposes. The departments in Washington are also reported to be short of an adequate supply, so much so that with the arrival of the recent warm spell the local trade at the capital had its entire stocks absorbed.

One jobber from there came to New York and placed an order for 1500 fans with a leading manufacturer for early shipment. This could not be complied with, but an effort was made to obtain as many as possible from the company's distributors, the remainder of the specifications to be made up and delivery promised in six weeks to two months.

In accordance with the statement of a leading manufacturer, whose output is an important factor, it will be impossible to get the material to keep the production of fans up to the demands of a normal season. It was made clear that last year, which recorded an unprecedented sale, every nook and corner of factories, warehouses, stores and even cellars was ransacked for fans in any condition that could be made salable. The result is that the market is bare. With this knowledge before them, distributors, territorial agents and jobbers in many instances doubled their orders for 1918.

Where a good stock of raw material is assured, more or less difficulty is being encountered in the retention of skilled workmen. Prices are now quoted f. o. b. local stocks for factory, and a change in price on new business may come along without previous notice. One manufacturer is known to have stocks exceeding last year's supply by 100 per cent in Eastern warehouses. Trouble is being found in obtaining priority shipping orders. A Philadelphia distributor requested an order for sixteen cars from a Middle West factory and was "turned down." A requisition for two cars by a New York house resulted in having an order for one granted and subsequently an order for the other. One manufacturer of prominence is not accepting any more business.

A Father's Mite—A Bond

METAL MARKET SITUATION

Supply of Copper Liberal—Wire Base Price Nominal—Tin Reaching High Figures

No uneasiness is expressed regarding the quantity of copper accessible and available for all purposes. So much is this the case that the arguments for a higher government price than 23.50 cents fell flat. One large producer in a report to his company last week said that the cost of mining and refining was 11 cents a pound. Wire base is quoted at 27 cents to 30 cents, which is nominal, actual sales for wire products being a case of negotiation. An authority states that "bare copper wire for electrical purposes, carloads and mill shipments, is quoted at 26 cents per pound base."

Tin, as far as spot may be quoted, is now over 90 cents per pound. A few lots of Chinese tin were sold last week at 91 cents, with 84 cents for April shipment. The market is unstable. Commandeering of all platinum by the government for the manufacture of electrical instruments and other war purposes is threatened. The War Industries Board has warned holders of the metal that not more than \$100 an ounce will be paid for commandeered platinum.

NEW YORK METAL MARKET PRICES

	April 15	April 22

Zinc, old scrap	5.50 to 5.62½	5.50 to 5.62½

THE WEEK IN TRADE

WITH a very fair volume of commercial business recorded in all parts of the country, government orders continue to dominate all lines in the electrical field. Deliveries have slightly improved, but the ever-present embargoes interfere greatly with the calculations of jobbers and dealers in keeping their stocks of staples and leading specialties in a normal condition. Delays in transportation are particularly acute in the Far West. Building operations are confined to necessities and those localities where war industries require unusual housing accommodations.

Sales are strong, in many instances heavy, on armored cable, conduit and large-size lamps, with enlarged transactions in renewable fuses, rubber-covered wire, sewing and washing machines. The fan situation is attracting attention, and a shortage is freely and frankly discussed as a possibility. A scarcity in certain staples is also evident. The curtailment of labor is causing concern, jobbers and dealers on the Pacific Coast stating that it is impossible to obtain and hold competent assistance.

Collections are encouraging, and credits are being limited and shortened to keep business in a liquid condition.

NEW YORK

In a general way business in the sale and distribution of electrical goods is very satisfactory. Manufacturing plants are running to capacity, some of them reducing accumulated contracts as the progressive transportation improvement, in the aggregate, makes freer deliveries of raw material and products possible. However, there is yet an inadequate supply of cars for both inbound and outbound tonnage. The factories, with scarcely a single exception, remain handicapped by the scarcity of experienced workmen, and the steadily increasing costs of production, through rising wages and other causes, apparently render further upward price revisions in some lines inevitable. Within the last month prices have been remarkably even.

Reports that the financing of the third Liberty loan was interfering with collections seem to be without substantial foundation. Credits, nevertheless, are firmly held up to the line of safety.

PORTABLE LAMPS.—Floor and table lamps are mentioned as fast sellers. Fine finishes and beauty of design prove attractive to jobber, dealer and ultimate consumer. Prices vary in accordance with these features.

COLLECTIONS AND CREDITS.—If collections have fallen off on account of investments in the drive to make the third Liberty loan an overwhelming success, it is not conceded in the electrical field.

HOUSEHOLD SPECIALTIES.—Warm weather lines are moving rapidly. A special effort on electrically equipped ironers and scrubbers of an improved type is bringing in satisfactory returns. The sale on toasters, grills, flatirons, sewing and washing machines and vacuum cleaners is far ahead of last year's record. Stocks are strong notwithstanding transportation difficulties.

FANS.—With the advent of a few warm days and others to follow in due course, the retail fan season has opened up with an unexpected showing of strength. Some manufacturers state that jobbers and dealers who have not "signed up" may be treated to a surprise in a raise of prices, as a shortage is generally conceded to be in sight.

LAMPS.—Supplies in all sizes are not so good as they should be, to repeat the statement of the largest jobbers. A shortage is still reported.

CONDUIT.—The larger sizes are particularly scarce. The smaller are in better supply, but not a great deal better.

DRY BATTERIES.—Stocks are reported to be in excellent shape. Deliveries are being made from factories in about ten days..

SMALL MOTORS.—Government demands for small direct-current motors, for use in the trenches abroad in connection with signaling devices, have nearly cleaned up the market, to quote one of the largest manufacturers. It is not easy, therefore, to deliver motors of 10 hp. under 60 to 120 days, which also applies to those of 2 hp. and below. On larger sizes of motors, from 25 hp. to 50 hp., where the frames are coming through or in stock, deliveries are better.

GLASS INSULATORS.—On April 1 glass insulators were advanced 10 per cent. The market is close and deliveries out of stock, but not guaranteed.

LOCUST PINS.—Conditions are very unsettled, changes in price occurring frequently owing to specifications for definite delivery dates. Quotations are \$2 to \$3 per 1000 higher, f.o.b. mill, with indications of a still further increase.

CHICAGO

Government business is coming to Chicago in larger volume. Apparently this is due to two things—first, the decentralized control of purchasing for the Ordnance Department; second, the lack of power facilities among the central stations in the East. An army officer at one of the ordnance depots in Chicago is responsible for the statement that the department here is doing a business of \$1,000,000 a day now, whereas only a little more than a year ago that business was about \$1,000,000 a year. Practically all of the officers in the Ordnance Department seem to recognize that the shortage of power exists in the East and that more business must be pushed into the Middle West. Vast quantities of warehouse space have recently been secured in Chicago through the aid of the Chamber of Commerce. It is expected that more will be needed, as the plan apparently is to continue production at top speed regardless of shipping, so that when the ships are available there will be no delay in sending the materials abroad. Even organized labor in Chicago seems to have awakened to the situation, as all of the building trade unions, including the electrical workers, have now signed a no-strike agreement for the duration of the war. Payments on government contracts are being speeded up, and this, it is expected, will have a good effect on the general collection situation. Jobbing business remains about the same, a spotty condition prevailing.

PINS AND BRACKETS.—Locust pins and brackets have taken another increase in price, amounting to from 10 to 20 per cent. Locust is very difficult to get, large quantities of it going into the war activities. Jobbers are being asked to push rock-elm pins and brackets.

CONDUIT.—Jobbers' stocks of conduit are still low. It is possible, however, to get good deliveries in some instances by carefully searching through the trade.

PORCELAIN.—Jobbers report that it is necessary to order about six months in advance and that manufacturers are not taking orders at stipulated prices, but are quoting only "price as of date of shipment."

SECOND-HAND MACHINERY.—Business for the last week has been rather slack, but indications are that it will take a sharp upturn, as inquiries during the latter part of this week have been very many. The repair shops of second-hand machinery places are exceptionally busy. It is predicted with considerable confidence that higher rates for repair of electrical machinery will shortly go into effect.

SMALL MOTORS.—Single phase, three-phase and direct-current motors of small sizes are moving in good volume. This includes motors up to 5 hp.

LIGHTING FIXTURES.—Business in lighting fixtures is decidedly off in volume. Some of the Chicago factories are bidding on such government business as trench mirrors and other small metal articles in order to occupy their factories.

BOSTON

The electrical trade is getting more and more "into phase" with the "win the war" movement each week. Although jobbers report a moderate recession in the volume of business, underlying conditions are held to be sound. Fairly good collections indicate this. Credits are closely watched, but a large amount of money is in circulation and a goodly share is flowing into the coffers of the electrical industry. Jobbers are getting ready to handle the immense amount of detail orders which will be required by the quartermaster's terminal now under construction at Boston. Preliminary wiring of field structures has begun and the rush of orders will soon be on. The shipyards are buying substantially, motors and wiring supplies being in great demand.

Stocks are generally in good shape and deliveries are improving, with the marked exceptions of conduit and porcelain.

FIXTURES.—Inquiries from summer home owners are coming in faster than was anticipated considering the quiet state of trade heretofore. A drive is also under way to capture the business of the summer hotel in connection with remodeling of old establishments. Prices show little change beyond an occasional shading to stimulate buying in the off-season period. Stocks are large and well adapted to varied requirements.

STORAGE BATTERIES.—A heavy demand for batteries is now being maintained by the automobile trade. The accumulation of stocks is very difficult as to local agencies. In some quarters an advance in the price of lead batteries would not be a surprise, in view of the increased prices lately put into effect by competing makes, but nothing definite is as yet given out on this. Government business holds up well.

MOTORS.—Deliveries are improving, one dealer stating that in a general way quotations have been reduced from a matter of months to a matter of weeks on shipments. Up to 50 hp. deliveries of from four to six weeks are not uncommon. Now and then motors slip into factory stock, but their tenure of residence is apt to be short. Unless advances in steel and copper occur before July well-informed opinion holds that motor prices will hold firm for the present. Shipyards are buying motors for both steel and woodworking tool service, air compressors, etc.

CONDUIT.—The situation continues discouraging. A recent inquiry for 3/4-in. pipe brought out the fact that the mill in question cannot start rolling this size until the last of May, making a three months' gap in this output from shipment to rolling. Long delays are prevalent in delivery of orders placed some time ago.

FANS.—Fans are going out to the retailer now in good volume. The jobbers continue to report receipts from the factories in carload lots.

POLE-LINE MATERIAL.—Very little buying is noted by central stations in comparison with peace times. Some orders are being handled in connection with energy supply to war service plants. Municipal purchases for fire-alarm work, etc., hold up well, but are, of course, small in volume compared with the normal absorption of the central stations.

ATLANTA

The large expenditures along governmental lines in the South during 1918 will create a greater market for electrical goods of all descriptions. That this condition will exist is borne out by the fact that somewhere in the neighborhood of \$275,000,000 has been appropriated for nitrate plants, shipbuilding yards and enlargements to military establishments, together with the development of those minerals which are vital to the winning of the war. Kingsport, Tenn., is proving to be a big center of activity in the munitions line, and a nitrate plant, with an accompanying industrial city, costing \$10,000,000, is now contemplated for this point, in addition to the manufacture of acetone and other by-products now under way. The War Department has also decided upon an outlay of \$20,000,000 for building piers and warehouses at Charleston, S. C. As the war has

greatly stimulated the demand for denatured alcohol from sawmill waste, a number of these plants in the lumber belt are being equipped.

The Lamb-Fish Lumber Company, Charleston, Miss., has let contracts for construction this week. Wilmington, N. C., has secured a million-dollar plant for concrete ship construction. Reports received from Washington indicate that it has been definitely decided to enlarge Camp Gordon to take care of 60,000 men, which will entail an expenditure of \$4,000,000. Other construction contemplated for Atlanta includes \$1,500,000 for additional hospital buildings at Fort McPherson and a reclamation plant employing 2500 men. Details for this plant are not available at this time.

ARMORED CABLE.—A big business has been recorded this week, and a number of the well-distributed stocks of the past few weeks have almost been cleaned out. Large quantities of this material have been shipped to Columbia, S. C., Jacksonville, Fla., and other cantonment centers. Inquiries reveal the fact, however, that the demand is from commercial sources, and there is no indication that any is being purchased for government account. Manufacturers report a scarcity of raw materials, at least temporarily, with an advance of 5 per cent in price. Two-wire, No. 14, is very scarce.

INCLOSED SAFETY SWITCHES.—Jobbers' representatives state that business in these shows a strong tendency. The demand has been accelerated by the activity of the inspection departments of a number of Southeastern cities, which have passed ordinances of a nature that facilitates sales. Shipments are reported as being very good.

RENEWABLE FUSES.—All the dealers and jobbers are securing some good orders and business seems to be increasing daily. Deliveries are excellent.

SEWING-MACHINE MOTORS.—Every one dealing in this appliance appears to be doing a very substantial business. The volume of sales is well ahead of the same period last year. One large jobber reports large sales on the complete outfits, which include sewing machine and motor. Deliveries are fair.

VACUUM CLEANERS.—The industry has experienced a larger trade in cleaners this spring than ever in the past.

SEATTLE

Prosperous activity is general among retail trade, with a gratifying reflex upon wholesalers. Specifically, in the past week the volume of sales was as satisfactory as during several weeks past. Sales to shipyards, as in the past, constituted the bulk of business transacted, although allied industrial plants did considerable buying. Orders for lumber mills show a slight increase. Government buying shows a decrease over last month.

Portland territory during the past week reports a large order for a complete electrical equipment for grain elevators, also the receipt of numerous inquiries for other elevators in contemplation in the Spokane territory. It also reports sales of electrical equipment complete for elevators in the Inland Empire. Portland jobbers report heavy sales of electrical machinery equipment and supplies to shipyards in Portland, Vancouver, Wash., and Astoria. Yards in Vancouver especially have been buying heavily lately.

The largest jobbing houses in the Northwest agree that the labor situation has never been equalled. The shortage of men, particularly of the draft age, is almost unbelievable. Jobbers report that warehousemen and clerks are impossible to obtain and hold. Retailers in many cases are resorting to female help. The electrical industry in all its various branches is seriously threatened. In Seattle particularly the shortage is most acute. The local traction company cannot secure men to operate the street cars and service is disorganized. The telephone company is hampered by a scarcity of outside men as well as of clerical force.

Difficulty in securing shipments of badly needed materials is causing anxiety. In several cases shipments have been en route for two months. L. C. L. shipments are particularly affected. Extreme shortages exist in rubber-covered wire, conduit and larger-sized lamps, and present indica-

tions are far from promising. The Seattle territory especially reports continued heavy sales of sewing machines and washing machines. Other domestic appliances are moving satisfactorily. Retailers report an increasing volume in the sale of house-wiring materials and fixtures, including chandeliers and shades. Electrical novelties are moving well. A slight increase in weatherproof wire is noted, the first increase mentioned for the past month.

The Northwest lumbermen feel that the curtailment of the government's wooden shipbuilding activities, tentatively announced recently, will not affect the fir lumber industry of the Northwest adversely.

SAN FRANCISCO

Business is very good and factory deliveries are better, save on conduit. A fair has been held at Davis, where farm plants and 32-volt appliances were featured. It was well attended and is expected to accomplish educational work. We are now in the year's first hot spell, which, coming as it does after a late rainfall, will hasten needed crops.

CONDUIT.—Conduit sales are slightly less than those of last year, but this is due to the difficulty of deliveries and the fact that many dealers were given an opportunity to stock on the old price basis. This is especially true of at least one of the largest shipbuilding plants, whose past purchases will carry it well on into 1918.

RUBBER-COVERED WIRE.—Jobbers report increased sales of rubber-covered wire, in some cases as high as 25 per cent over last year's showing.

FANS.—Dealers are found to be very cautious in estimating their requirements for the 1918 season, complaining in general that they carried over unusually large surpluses from last year's stock and do not anticipate a normal demand this year; but those whose position enables them to survey the entire field are positive that this will be a good fan year, principally because of the widely scattered industrial plants (especially canneries in the central valleys) that have been hastily constructed with practically no provisions for ventilation.

INSULATING MATERIAL.—The United States government is requiring plenty of fiber, and the shortage of large motors, which makes much rewinding imperative, causes it to requisition much cotton tape and insulating compound. Deliveries are now very good, even of cotton tape, which has been practically an unknown quantity for months past. The market on silk tape is upset, owing to unexpected survivals of stock purchased at former prices, which were very small in proportion to those now effective.

HEATING DEVICES.—Present demands are rather poor and surplus stocks are on hand. Flatirons are selling at a little less than the normal rate, but devices such as toasters and percoiators are barely moving. It is evident that more intensive effort must be made before the real buying public is reached. One of the best selling heating devices is the heating pad, on account of a considerable amount of prevalent sickness. The unusually warm and dry winter spoiled the radiator season.

WASHING MACHINES.—The demand for washing machines is better than ever and is to be further stimulated by billboard displays. Prices have just advanced so that washers for the average household now list at \$115 in place of \$105, and washers for small families have jumped from \$80 to \$90 each. In spite of this fact the demand is good.

DRY BATTERIES.—Dry-battery sales are running about 20 per cent above those of last year, owing to the increasing number of electric trucks, long haul requirements, and, of course, the ever-increasing number of automobiles in service. The United States government, for instance, hauls a large portion of its requirements by its own fleet of motor trucks from San Francisco.

FLASHLAMPS.—Flashlamp sales are excellent. Deliveries are very good on account of the Pacific Coast factories for the manufacture of renewals. The presence of thousands of soldiers, many of whom have been generously remembered by gifts of flashlamps, augments the steady battery demand.

Current Prices of Electrical Supplies

New York and Chicago Quotations

THE prices quoted are those prevailing in standard packages of specified lots on apparatus and appliances in Eastern and Middle West markets at the beginning of business on Monday of this week. They are in all cases the net prices or prices subject to discounts from standard lists of contractors, central stations, dealers and others engaged in the resale of such goods.

Prices in Southern and other nearby markets will rule about the same as those in the Middle West, although slight modifications to cover increased freight and local demands should be expected. In the Far West and on the Pacific Coast the prevailing prices are naturally higher, covering as they must increased

freight and the necessity of larger stocks with increased interest and warehouse charges on account of the distances from sources of supply, infrequent turnover of stock and uncertainty as to delivery of goods in transit. Moreover, the Far West presents a wide variation in demand due to a small population spread over a wide area in agricultural and mining communities, as contrasted with the denser population of the East and Middle West, their nearness to the sources of supply, the more frequent turnover in stocks and the constant demands which arise in industrial centers. Price variations may be due to difference in grade of products of different manufacturers, to local conditions, or to both.

NEW APPARATUS & APPLIANCES

A Record of Latest Developments and Improvements
in Manufacturers' Products Used in
the Electrical Field

Coal Conveyor That Requires Only One Man to Operate

A mechanical conveyor that will load and unload auto-trucks and wagons very quickly is being manufactured by John F. Godfrey of Elkhart, Ind. A single-rope overhead cable is employed to support the bucket. The conveyor can be operated by one man, who loads the bucket directly from the truck, hoists it to another truck or to the storage pile. The conveyor bucket runs along the cable until it reaches a movable trip and there empties its load upon the pile. It is claimed that in a hundred feet of cable length, 1000 tons of coal can be stored by this device.

Medium-Service Electric Truck

A three-wheel tractor designed for service of a character between that accomplished by the carrier truck and the heavy-duty tractor is being manufactured by the Elwood-Parker Electric Company of Cleveland, Ohio. The most distinctive feature of this tractor is the single front wheel, which is steered by a hand-wheel or hinged lever on the body of the tractor. When the wheel steer is used the control lever is placed on the left of the column, but when the lever steer is installed the control lever is provided at the side of the operator's seat as shown in the accompanying illustration. The tractor cannot be started from the floor because the seat operates a circuit breaker which closes when the operator's weight presses on the seat. The battery is

OUTSIDE TURNING RADIUS LESS THAN THE
LENGTH OF THE TRACTOR

arranged so that the weight is over the drivers.

Solid wheels as well as solid rubber tires are provided, and the tractor has a normal drawbar pull of 300 lb. (136 kg.) and maximum pull of 850 lb. (385 kg.) The speed at no load is

625 ft. (190 m.) per minute. Its length is 40 in. (101.6 cm.) and its width 41 in. (104.1 cm.). The outside turning radius is less than the length of the tractor.

Adjustable Spray-Head for Cooling Tanks

A spray-head equipped with convenient adjusting gear that can be actuated from the shore is being manufactured by the Yarnall-Waring Company, Chestnut Hill, Philadelphia. Referring to the diagram produced herewith, *A* indicates the cast-iron body of the device to which a 3.25-in. (8.2-cm.) bronze tube, *B*, is secured. A helical opening of coarse pitch is cut in the tube through which the sprayed water leaves the nozzle at

SPRAY-HEAD WITH ADJUSTABLE WATER
APERTURE

an angle of 60 deg. to the axis of the tube. By moving the bar *J* to the left the cap *C* is pressed against the helically slotted tube, thus reducing the slot opening through which the water issues.

The manufacturer claims that the maximum cooling effect is obtained under all conditions of temperature and humidity, that the minimum loss of water by driftage due to wind results, and that a high efficiency is obtained at fractional loads by the use of this spray-head.

14,000-Kva. Single-Phase Transformer

The accompanying illustration shows the framework and bracing arrangement of a large single-phase transformer recently manufactured by the Westinghouse Electric & Manufactur-

ing Company of East Pittsburgh, Pa. The transformer is rated at 14,000 kva., 60 cycles and 150,000 volts. The transformer, which is of the shell type, has

LARGE SINGLE-PHASE TRANSFORMER DE-
SIGNER FOR 150,000-VOLT SERVICE

a 25 per cent overload rating, which gives a maximum rating of practically 17,500 kva. The top and bottom ends of the coil are held against distortion by two heavy steel plates reinforced by four lengths of angle iron riveted to them. These angle-iron plates are held together by four heavy tie-rods. The transformer tanks are made of heavy boiler plate, all seams being oxy-acetylene-welded. The tank is supported by a structural-steel base equipped with wheels. The high-tension terminals are of the condenser type protected by means of a number of porcelain rain shields to adapt them to outdoor service. The transformer is 23 ft. 6 in. (7.2 m.) over all in height, and weighs, complete with oil and fittings, about 110,000 lb. (49,895 kg.).

Sensitive Lightning Arrester for Pole Transformers

A multi-gap shunt-resistance lightning arrester in which the gaps shunt the resistance has been developed by the General Electric Company, Schenectady, N. Y. The arrester is of the compression-chamber type and is adapted for the protection of distribution transformers. By mounting the combination of gaps and shunt-resistance rods in porcelain tubes a high degree of sensitiveness to lightning disturbances is obtained. It is claimed that the arrester will discharge with small increases in potential, will divert lightning disturbances having a wide range of frequency and will quickly cut off

the dynamic power supply after the transient disturbance has passed. It also prevents grounds and "shorts" on the transformer.

Numerous paths are offered for the discharge of lightning through the arrester by the four units of shunting resistance used. As the resistance rod shunted across the series gaps is grounded through the other resistances, the initial discharge is minimized. The path which the discharge travels after passing through the series

gaps depends on the frequency and power back of the discharge. Very high frequency will cause a discharge straight across all the gaps, whereas discharges of lower frequency will take place through one of the shunt paths. The generator current which tends to follow the lightning discharge will be diverted through the resistance rods and thereby limited to a value that can be readily extinguished by the gaps.

Testing Blocks That Assure Accurate Results

A terminal block for use in testing electrical machinery which, it is claimed, will assure accurate results has been developed by the Metropolitan Engineering Company, 35 Vestry Street, New York City. The device consists of phosphor-bronze clips mounted on a porcelain block in such a manner that opposite sides of the clips are connected

BLOCK PERMITS CONNECTION OF METERS WITHOUT INTERRUPTING SERVICE

to the corresponding incoming and outgoing circuits. The outline diagram presented herewith shows the portion of the testing block which is permanently installed in the circuit, and above it the portable portion to which the testing meters are connected.

The current-tapping blades on the portable portion consist of phosphor-bronze strips separated by a thin layer of micarta insulation. The meters are connected across the bronze strips so that when the blades are inserted in the clips on the testing block the meters are connected in series with the circuit. The middle terminal of the three-phase portable block shown is a potential tap and also consists of a strip of bronze. By using this block for testing the necessity of making temporary connections with wire jumpers is avoided, fire hazard is reduced, and the necessity of stopping a machine to insert meters is eliminated.

Outdoor Fuse and Disconnecting Switch

A combined fuse and disconnecting switch for use with transformers where no primary switches are used is being manufactured by the General Electric Company, Schenectady, N. Y. The fuse is suitable for interrupting the exciting current of transformer banks rated at

EXPLOSION WHEN FUSE BLOWS AND EXTINGUISHES ARC

not more than 300 kva. To open the circuit the holder is lifted completely out of the contacts by the fuse hook handled from the ground. The upper end of the fuse holder can be hung from the cap which partly surrounds the lower contact clips when the switch is open. To close the circuit the upper contact of the holder is inserted in the upper clips first and the lower contact is then pressed into the lower clips by the hook.

The fuse holder has petticoats spaced so as to provide ample creepage surface. The brass contact parts at the ends of the fuse holder engage with the stationary contacts on the supporting insulators when the holder is in normal operating or closed position.

The contacts are protected against the effects of ice, sleet and snow by the hood attached to the top of each supporting insulator and by the relative position of the parts. The fuse element passes through the center of a fiber tube within the porcelain fuse holder and is attached to the upper closed end of the fuse holder by means

of an adjustable clamp and to the lower open end by a circular ring. When the ring is tightened it holds the fuse firmly in place and prevents it from shearing off when the element blows. The expansion of the gases formed, occurring after the fuse has ruptured, effectively expels the arc through the open end of the holder in a downward direction, thereby opening the circuit. New fuses may be readily inserted.

The device is listed as the type TD-127 and is made in single-pole units for vertical mounting on flat surfaces. It can be obtained for use on 15,000, 22,000, 35,000 and 45,000-volt circuits with a maximum current rating of 50 amp. No special arrangements are needed for mounting. The supporting bracket is bolted to the cross-arm of the supporting structure.

Lightning Protector for Substation Telephone Circuits

A self-cleaning saw-tooth lightning arrester is being manufactured by the Reliable Electric Company, 411 South Sangamon Street, Chicago. The protectors, which have been approved by the National Board of Fire Underwriters, consist of copper blocks entirely inclosed by covers that surround the fuses as well as the rest of the lightning arrester. The fuse cases are made of tubular fiber, tubular magnesia, tubular wood, flat wood, folded mica or folded fiber. They can be easily re-wired.

Motor-Driven Washing Machine

A motor-driven washing machine which is equipped with an extra pulley that can be used to drive water pumps, turn ice-cream freezers and other small

WASHING MACHINE HAS EXTRA PULLEY FOR DRIVING OTHER MACHINERY

machinery has been brought out by the Haag Brothers Company of Peoria, Ill. The washing machine, known as the "Nuway," is of the dolly type and is equipped with a varnished wood tub finished in natural color. The supporting platform is made of steel.

Trade Notes

Bryant Electric Company's Sales Department Personnel

The Bryant Electric Company of Bridgeport Conn., has announced the personnel of its sales department as follows:

JOHN R. TOTTING, connected with the Chicago office for more than twenty years, is continued as assistant manager.

FRANK V. BURTON has been appointed general sales manager, a post just established. His connection with the company covers sixteen years, he having been Eastern sales manager for the last eleven years.

HAROLD E. SANDERSON, Pacific Coast manager at San Francisco, Cal., for the last eight years, continues in that capacity, but this office will now report direct to the general sales manager instead of being a subsidiary of Chicago.

ROBERT M. EAMES is appointed export manager, with headquarters at Bridgeport. He has been with the company for twelve years and for more than a year past has been devoting most of his attention to this department of the company's business.

WILLIAM A. STACEY, field representative of the company in the Middle West for the last ten years, becomes Western manager, succeeding to the vacancy caused by the death of Edward K. Patton, mention of which was made in the ELECTRICAL WORLD of March 30.

THE SUNDH ELECTRIC COMPANY, manufacturer of controlling devices, of New York City, announces a change of address from New York to Newark, N. J., the Newark address being Avenue C and Parkhurst Street, and the New York office 51 East Forty-second Street.

THE SHAWINIGAN ELECTRO-METALS COMPANY of Montreal, Can., maker of magnesium, has established a sales office in Cleveland, Ohio, with Detroit, Chicago, Buffalo, Pittsburgh and other points as tributary territory. D. P. Falconer, sales agent, has his office at 932 Leader-News Building.

THE NATIONAL BANK OF COMMERCE of New York City is distributing a new book entitled "Export Trade Associations." The publication contains the complete text of the Webb act, approved April 11, and an official summary of the report of the Federal Trade Commission on the development of foreign markets. Copies may be had on application.

THE WILLIAM F. WOLFF COMPANY of New York City has appointed the S. W. Electrical Company, 144 East Thirty-fourth Street, sole distributor of the "Anywhere" lamp brackets, under the management of William F. Wolff, effective May 1. The S. W. company intends appointing sales agents in the principal cities to handle wholesale and retail business.

THE GENERAL DEVICES & FITTINGS COMPANY has moved its office from 817 West Washington Street to the Mid-City Bank Building, Halsted and Madison Streets, Chicago. The factory will remain at the old location and will be enlarged to take in the space formerly occupied by the offices. This change was necessitated owing to the large increase in business.

THE BOSCH MAGNETO COMPANY of Plainfield, N. J., and Springfield, Mass., has been taken over by the government. A. Mitchell Palmer, alien property custodian, will name a new board of directors. It is officially announced that an investigation showed that the company was owned entirely in Germany. The real valuation of the property is said to be about \$7,000,000, although it was capitalized at only \$75,000.

HERBERT A. JACKSON has been elected president of the Chicago Pneumatic Tool Company of Chicago, to succeed W. O. Duntley, resigned. Mr. Jackson has for some time been connected with the Bethlehem Steel Corporation and was more recently head of its Boston office. He has had charge of the sales in that territory, and it is considered probable at Chicago that he will readjust the sales methods of the Chicago company.

THOMAS M. CLULEY, who has been associated with George W. Provost, president of the Union Electric Company, for the last twenty-two years, resigned his position on April 1 and joined the forces of the W. A. McCombs Company, Pittsburgh, Pa. The W. A. McCombs Company manufactures "Maco" safety switches. It is territorial representative of the following manufacturers: American Brass Company,

American Circular Loom Company, Atlantic Insulated Wire & Cable Company, Delta-Star Electric Company and Page & Hill Company.

FRANK E. WATTS has gone into business for himself as manufacturer's agent at 30 Church Street, New York City. He will continue to represent the Hart Manufacturing Company, for which he has been New York district manager since the beginning of 1915, and in addition has taken on the lines of the following companies: Electric Fuseguard Company, Wadsworth Electric Manufacturing Company and Worth Manufacturing Company. His territory will cover Virginia, District of Columbia, eastern Maryland, Delaware, eastern Pennsylvania, New Jersey and New York State.

THE PHOENIX ELECTRIC COMPANY, Mansfield, Ohio, now occupies a new modern two-story brick building, fully equipped. A. C. Linzee, proprietor, secured possession of the plant about two years ago, going from Akron, Ohio, and having been designing engineer for the General Electric Company. He has developed a line of alternating-current motors, which will be manufactured on a large scale at the new plant. The increased business of the company made it necessary to secure new quarters and the new building is the result. The plant is fully equipped for the expansion of the business, which has had steady growth and during the past two years has nearly doubled.

Trade Publications

LAMPS.—A circular being distributed by the Waterbury-Wallace Company, Inc., describes the "Wallace" portable lamp.

STOKERS.—Laclede-Christy, Railway Exchange Building, St. Louis, has issued a new catalog describing and illustrating its chain-grate stokers.

ATTACHMENT PLUG.—The Mueller Electric Company of Cleveland, Ohio, is distributing a circular describing its "At-tacho" plug for electric appliances.

LAMPS.—"A Light Which Beats Daylight" is the title of a paper by E. L. Elliott which is being distributed by the Cooper Hewitt Electric Company, Eighth and Grand Streets, Hoboken, N. J.

BALL BEARINGS.—The Norma Company of America, 1790 Broadway, New York, has issued a circular describing its ball bearing for fractional horsepower motors. The various features of the ball bearing are given.

FUSES.—A. F. Daum of Pittsburgh, Pa., is distributing a circular describing and illustrating the Daum refillable cartridge fuse for electric light and power installation. The method of reloading the fuses is illustrated in the folder.

ELECTRIC HOUSE PUMPS.—The "Buckeye" electric house pump for cisterns and shallow wells is described in a bulletin distributed by Mast, Foos & Company of Pittsfield, Ohio. Illustrations of the pump are given and the construction features recounted.

BRASS FITTINGS.—The Ohio Brass Company of Mansfield, Ohio, has issued supplement No. 1 of its general catalog No. 16, describing and illustrating its brass fittings for electric railway and mine haulage construction. High-tension porcelain insulators are also described in the bulletin.

MECHANICAL RECTIFIERS.—The Breco Electric Company of Toledo, Ohio, is distributing a bulletin describing the Breco converter for rectifying alternating current. Converters for furnishing direct current to operate electric tools, etc., and for service stations and garages where large capacities are required are illustrated and described in the booklet.

FIBER AND PAPER INSULATION.—The National Fibre & Insulation Company, Yorklyn, Del., has issued a bulletin entitled "Vulcanized Fiber and Insulation Paper" that describes the "Old Hickory" fiber and "Peerless" insulation. The bulletin is illustrated with photographs showing the bushing, gear and gear blank and other products of the company. In the back of the booklet tables of useful formulas are presented.

BOWLS, GLOBES AND REFLECTORS.—The Ivanhoe-Regent Works of the General Electric Company, Cleveland, are distributing catalog No. 257, descriptive of the "Regent" bowls, globes and reflectors for commercial and ornamental illumination. Semi-indirect illumination for offices, schoolrooms and drafting rooms is discussed and general engineering data, including photometric curves and detailed illumination curves for various lamps and

reflectors, are given. Illustrations of the "Regent" shades and holders are included.

ELECTRICAL EQUIPMENT FOR CEMENT MILLS.—This is the title of a publication issued by the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa. The pamphlet illustrates the interior of a motor-driven cement mill. Numerous photographic reproductions are given that show the application of motors to various types of machinery employed in cement mills. Advantages of motor drive for this class of service and characteristics required by motors to be specially successful are briefly discussed in the bulletin.

New Incorporations

THE ILLINOIS SOUTHERN POWER COMPANY of Chicago, Ill., has been incorporated with a capital stock of \$2,500 by Henry M. Brooks, Mack E. Gillis and P. L. Miller.

THE FRANCONIA ELECTRIC LIGHT & POWER COMPANY of Souderton, Pa., has been granted a charter with a capital stock of \$5,000. S. F. Muzzy is interested in the company.

THE NEW ENGLAND ELECTRIC LAMP COMPANY of Danvers, Mass., has been chartered with a capital stock of \$25,000. O. R. Bodwell is president and William A. Webb is treasurer.

THE OSKALOOSA (IOWA) POWER COMPANY has been incorporated with a capital stock of \$5,000. The officers are: C. B. Vermillion, president, and Code M. Vermillion, secretary and treasurer.

THE SOUTHERN CITIES POWER COMPANY of Chattanooga, Tenn., has been incorporated by George B. Adams, G. W. Irwin, J. C. Stickney, J. H. Roymer and John R. Evans. The company is capitalized at \$50,000.

THE ATTICA (IND.) ELECTRIC & SUPPLY COMPANY has been incorporated by J. W. Harrison, Charles W. Zeigler, John T. Nixon and Floyd E. Poston. The company is capitalized at \$50,000 and proposes to generate and distribute electricity.

THE LEGAL LEVEL LIGHT COMPANY of Rochester, N. Y., has been chartered by D. T. Roach, I. Smith and T. B. Shanahan of Rochester, N. Y. The company is capitalized at \$20,000 and proposes to manufacture automobile headlights, etc.

THE KANAWHA CENTRAL POWER & SUPPLY COMPANY of Olcott, W. Va., has been chartered with a capital stock of \$100,000 to generate and distribute power. The incorporators are: S. B. Avis, Ivory C. Jordan, N. F. Young, John A. Thayer and F. A. Avis of Charleston.

THE AUTO ELECTRIC SERVICE COMPANY of Toronto, Ont., has been incorporated by George J. Beattie, 72 Victoria Street; Ivan R. Church, Rudolph P. Caulford and others. The company is capitalized at \$40,000 and proposes to manufacture electrical apparatus, machinery, etc.

THE DOMINION LAND COMPANY of Montreal, Que., Canada, has been incorporated with a capital stock of \$100,000 to manufacture electrical supplies, lamps, motors, engines, etc. The incorporators are: Philip H. Klein of Westmount, Que.; Henry B. Irving, Edson G. Place and others.

THE COMMONWEALTH PUBLIC SERVICE COMPANY has filed articles of incorporation under the laws of the State of Delaware with a capital stock of \$500,000 to generate and distribute electricity. The incorporators are: M. M. Clancy, C. L. Rimlinger and F. A. Armstrong of Wilmington, Del.

THE UNILECTRIC COMPANY OF CANADA, LTD., of Edmonton, Alta., Canada, has been incorporated with a capital stock of \$25,000 to manufacture electrical supplies, equipment, motors, etc. The incorporators are: Chester McMann, Joseph R. Ulery of Edmonton, Godfrey H. Beaudry of Wainwright, and others.

THE INTERURBAN ENGINEERING COMPANY of Toronto, Ont., has been incorporated by Edwin Smiley, 17 Thornburn Avenue, Toronto; Bruce Williams, Bank of Hamilton Building; Wesley Rhodes and others. The company is capitalized at \$35,000 and proposes to manufacture machinery, motors, electrical apparatus, etc.

THE GREAT WEST ELECTRIC COMPANY of Winnipeg, Man., has been incorporated with a capital stock of \$300,000 by Sidney T. Smith, William R. Ingram, James N. Hutchison and others. The company proposes to generate and distribute electricity for lamps, heaters and motors; also to manufacture electrical equipment.

New England States

BATH, ME.—The Central Maine Power Company is extending its feed wires from a plant near the Chops to the pumping station at Nequasset, which is to be equipped for electrical operation soon.

CAVENDISH, VT.—Negotiations have been completed between the Colonial Power & Light Company of Claremont, N. H., and the Cavendish Electric Power Company whereby the former will supply electricity (100 kw.) to the latter. Plans have been prepared for the construction of a new substation.

HARTFORD, VT.—Preliminary plans have been prepared by the New England Telephone & Telegraph Company, 50 Oliver Street, Boston, Mass., for the construction of a new telephone exchange building at Gates and Currier Streets, in the White Junction district of Hartford.

BROCKTON, MASS.—Work will soon begin on the installation of the ornamental lighting system on Main Street, in the business center, School and Centre Streets, and City Hall Square. Orders have been placed for the material for the proposed work.

FALL RIVER, MASS.—The Fall River Electric Light Company has petitioned the Massachusetts Board of Gas and Electric Light Commissioners for permission to issue \$700,000 in capital stock, the proceeds to be used for erecting an electric transmission line to connect the company's plant at Fall River with the wires of the New England Power Company and for enlarging the Hathaway Street plant.

MILFORD, MASS.—The Milford & Uxbridge Street Railway Company is installing a 300-kw. generator at the station of the Worcester Suburban Electric Company for the purpose of supplying electricity to its line between Uxbridge and Milford.

NEWBURYPORT, MASS.—Plans are being considered for the construction of an addition to the new electric plant of the Newburyport Gas & Electric Company on the former Fiberloid wharf, to provide space for the installation of a 2000-kw. electric generating unit, with a condenser pump, boilers and other apparatus.

NEW BEDFORD, MASS.—The City Council is considering some changes in the ornamental lighting system on Purchase Street. It is proposed to erect the type of lamp used on Washington Street south to School Street and north of Maxfield Street, calling for the installation of 23 additional lamps. Nothing will be done until the end of the war. William P. Briggs, superintendent of street lights, was instructed by the Council to prepare and submit a sketch for a lighting scheme for Acushnet Avenue from Ball's Corner to Belleville Road.

TAUNTON, MASS.—The special committee appointed to look into the needs of the municipal electric-light plant has engaged C. W. Whiting of Boston, consulting engineer, to advise the City Council and the management as to the condition of the plant and what is needed to put it in a position to meet the demands of increasing business.

HARTFORD, CONN.—A permit has been granted to the Arrow Electric Company for the construction of a factory, 55 ft. by 135 ft., three stories high, on Hawthorn Street, to cost \$55,000. W. J. Sexton has the contract for building. Ford, Buck & Sheldon are architects.

NEW HAVEN, CONN.—The United Illuminating Company has been granted a permit for the construction of an addition to its plant on Grand Avenue, to cost about \$6,000.

NORWALK, CONN.—The ornamental lighting system on South Main Street will be extended as far as Monroe Street soon.

STAMFORD, CONN.—Plans have been prepared by the Stamford Electric & Manufacturing Company for further extensions to its plant. The company manufactures electric motors and has recently completed the erection of a large two-story factory. It is proposed to build another similar building and to make extensions to the present building.

Middle Atlantic States

BUFFALO, N. Y.—The Transmission Ball Bearing Company, 1050 Military Road, Buffalo, is considering the erection of an addition, 175 ft. by 350 ft., to its plant, to cost about \$150,000.

DUNKIRK, N. Y.—The Council has appropriated \$7,000 for the purchase of ornamental street lamp fixtures, the cost of the installation and maintenance to be met by the water board. The type of lamp has not yet been decided upon.

Construction

News of Projects, Plans, Bids and Contracts. Notes on Work Under Way

ELMIRA, N. Y.—The Public Service Commission has directed the Elmira Water, Light & Power Company to erect an electric transmission line to Moutour Falls and to supply electricity to residents in that village.

GLENS FALLS, N. Y.—The Adirondack Electric Power Corporation is planning to construct a power house at Glens Falls, to cost about \$100,000. The company is also contemplating the construction of a power station in the vicinity of Schoharie later on.

GROTON, N. Y.—The Groton Electric Power Company has petitioned the Public Service Commission for permission to construct an electric-light plant in Groton and for an approval of franchise granted by the village.

LONG ISLAND CITY, N. Y.—A. J. Buschmann Company, 461 Eighth Avenue, New York, has been awarded contract for all electrical work in connection with the new addition to the plant of the Welin Marine Equipment Company, 312 Vernon Street, now under construction. The cost of the building is estimated at \$25,000.

NEW YORK, N. Y.—The capital stock of the A. L. Shemel Company, 60 East 116th Street, has been increased from \$30,000 to \$75,000. The company manufactures electrical supplies.

ROCHESTER, N. Y.—Contract has been awarded to A. Frederick & Sons Company, 710 Lake Avenue, Rochester, by the Board of Contract and Supply for the construction of a new power plant.

ROCHESTER, N. Y.—Preparations are being made by the Mayer Coating Machine Company of Rochester for the erection of a factory, 2 miles outside of the city limits. The company, it is reported, is in the market for equipment for an automatic steam engine plant. The company manufactures paper-coating machinery.

GLOUCESTER CITY, N. J.—Plans are being considered by the Public Service Electric Company for the installation of a new conduit system, for electric wires, in Market Street, beginning at its local power house and extending to King Street. The City Council has granted the company permission to install the system.

MORRISTOWN, N. J.—The installation of new motor equipment in the local schools for operating the ventilating system is under consideration by the board of education.

NEWARK, N. J.—Plans have been prepared by the Natural Carbonic Gas Company, McClellan Street, for the construction of a boiler plant, to cost about \$10,000.

NEWARK, N. J.—Bids will be received by the Board of Freeholders for the installation of a new water tube boiler at the Essex County Hospital at Overbrook. Thomas W. Smith is chairman of the committee on public buildings.

NEWARK, N. J.—The Northern Leather Works & Produce Company, 377 Broadway, New York City, has awarded contract to H. W. Franklin, 110 Fort Greene Place, Brooklyn, N. Y., for the construction of a new power house at its local plant on Backus Street.

RAHWAY, N. J.—The National Pneumatic Company, 50 Church Street, New York City, is contemplating the construction of a new building, 200 ft. by 300 ft., on New Brunswick Avenue. Rahway, which will be equipped as a machine shop and for general manufacturing purposes.

WEEHAWKEN, N. J.—Plans are being considered by the Weehawken Tungsten Lamp Company, 550 Gregory Avenue, for the reconstruction of its brick and iron lamp manufacturing plant, recently destroyed by fire, causing a loss of about \$25,000.

ALTOONA, PA.—The Penn Central Light & Power Company has filed notice with the Public Service Commission of an issue of \$75,000 in bonds, the proceeds to be used for extensions and improvements to its plant and system.

GREENVILLE, PA.—Notice has been filed with the Public Service Commission by the Mercer County Light, Heat & Power Company of an issue of bonds to the amount of \$100,000, the proceeds to be used for extensions, improvements, etc.

HAZLETON, PA.—Plans have been completed for equipping the Oneida slope of the Lehigh Valley Coal Company of Hazle-

ton for electrical operation. Energy to operate the mine will be supplied by the Harwood Electric Company of Hazleton.

PHILADELPHIA, PA.—Plans have been prepared by the Philadelphia & Reading Railroad Company for the construction of a new power house, 45 ft. by 75 ft., at Tulip and Somerset Streets.

PHILADELPHIA, PA.—Plans are being prepared by the Bell Telephone Company for additions and improvements to its telephone building in Germantown. John T. Windrim, Commonwealth Building, is architect.

WILLIAMSBURG, PA.—Notice has been filed with the Public Service Commission by the Penn Central Power & Transmission Company of an issue of \$50,000 in bonds, the proceeds to be used for extensions and improvements to its system.

WILMINGTON, DEL.—The turbine room at the plant of the Wilmington Gas Company, foot of Madison Street, was recently destroyed by fire, causing a loss of about \$25,000.

WILMINGTON, DEL.—Notice has been filed with the Public Service Commission by the National Electric Service of a change in its name to the Brokaw-Eden Manufacturing Company, and an increase in capital stock from \$500,000 to \$1,000,000.

FREDERICK, MD.—The Hagerstown & Frederick Railway Company has submitted a plan to the Mayor and Aldermen for lighting the streets of Frederick. Two proposals were submitted, the city to have the option of taking either, under a contract for one, two or three years, or practically any time it sees fit, the contract to be terminated upon a notice of a certain length of time. The first is to light the city at a cost not to exceed \$7,200 per year, exclusive of the College Park, and not to exceed \$7,500 per annum, including College Park. The other is for the city to learn the cost of operating the municipal plant from April 1, 1917, to April 1, 1918, and no matter what this amount might be the company would guarantee to furnish the service for the same figures, less \$2,000. It is not proposed to dismantle the municipal plant. The plans provide for the installation of a motor in the city plant and to utilize energy from the plant at Security and water power at Dam No. 5.

PARKERSBURG, W. VA.—The Parkersburg Iron & Steel Company has begun work on the construction of an addition to its power plant, 30 ft. by 45 ft., to cost about \$12,000.

WILCOE, W. VA.—The Norfolk & Western Railroad Company is planning to rebuild its machine shop in Wilcoe, recently destroyed by fire.

NORFOLK, VA.—Plans have been filed and contract awarded to Nicholas & Linderman, Seaboard Bank Building, Norfolk, for alterations and improvements to its electric substation, to cost about \$11,000.

RICHMOND, VA.—The capital stock of the Williams Power Company has been increased from \$50,000 to \$150,000, the proceeds to be used for extensions and improvements.

RICHMOND, VA.—Hackley Morrison, Moore Building, 16 North Ninth Street, Richmond, Va., it is reported, would like to receive prices (dealers') on a 75-kw., 125-volt direct-current generator, directly connected to generator; could use a turbo-generator of same rating.

WASHINGTON, D. C.—The United States Shipping Board, 1319 F Street, N. W., is planning to erect a five-story building, to have 500,000 sq. ft. of floor space, for which \$5,000,000 has been appropriated.

WASHINGTON, D. C.—Contract has been awarded by the Bureau of Yards and Docks, Navy Department, Washington, D. C., for construction of substation and frequency-changer house to the Dawson Construction Company, May Building, Pittsburgh, Pa., at \$52,520.

WASHINGTON, D. C.—Contract has been awarded by the Chesapeake & Potomac Telephone Company, Thirteenth and G Streets, N. W., to Andrew Murray, 729 Twelfth Street, N. W., Washington, for remodeling its exchange buildings at 1420 Columbia Road and at 629 B Street, to cost \$60,000 and \$15,000 respectively; and also for a third exchange building at another location.

WASHINGTON, D. C.—The contract for construction of the building for the Washington Athletic Club is reported to have been awarded to the Longacre Construction Company, Widener Building, Philadelphia, Pa. The building will be 138 ft. by 150 ft., 12 stories high, and will cost about \$650,000. Milburn, Heister & Company, Union Savings Bank Building, Washington, are architects.

North Central States

DETROIT, MICH.—The Detroit United Railway Company is planning to build an extension to the Ford plant on the River Road.

GRAND RAPIDS, MICH.—The Lewis Electric Company of Grand Rapids has been awarded a contract for the installation of lamps and motors in the new Haskell plant near Euler Station. The contract calls for wiring and the installation of 3.0 nitrogen lamps of 3.0 cp. each and 3.5 Wagner motors.

RYAN, OHIO.—Improvements are contemplated to the municipal electric-light plant and water-works system, involving an expenditure of about \$10,000.

CLEVELAND, OHIO.—The capital stock of the North Electric Company has been increased from \$135,210 to \$210,000.

COVINGTON, OHIO.—The capital stock of the Buckeye Light & Power Company has been increased from \$10,000 to \$60,000.

DAYTON, OHIO.—Resolutions have been adopted by the City Council providing for the installation of an ornamental lighting system on East Second Street between Jefferson and St. Clair Streets.

FRONTON, OHIO.—The Fronton Incandescent Light & Supply Company is contemplating building an addition to its plant at First and Chestnut Streets.

LORAIN, OHIO.—The American Ship Building Company is erecting a large power house in connection with extensions to its plant, which include a new boiler shop, machine shop and other new departments. The cost of the power house is estimated at \$200,000.

MANSFIELD, OHIO.—The capital stock of the Richland Public Service Company has been increased from \$10,000 to \$3,200,000.

NELSONVILLE, OHIO.—The Hocking-Sunday Creek Traction Company is planning to build a new substation. A new rotary converter, it is reported, has been purchased by the company.

SANDUSKY, OHIO.—The Sandusky Gas & Electric Company has entered into a contract with the Erie Window Glass Company for an initial installation of electrical power, which will ultimately lead to larger demand for electricity.

SHELBYVILLE, KY.—Surveys are being made by the Frankfort & Shelbyville Traction Company for the construction of its proposed electric railway between Frankfort and Shelbyville, a distance of about 20 miles. Pending the construction of its own power plant the company will purchase energy to operate the system from a nearby central station. L. G. Smith of Shelbyville is president.

EVANSVILLE, IND.—The capital stock of the Schroeder Headlight & Generator Company has been increased from \$150,000 to \$250,000. The company has taken over the plant of the L. B. Jones Company of Kansas City, Mo., manufacturers of farm electric plants.

INDIANAPOLIS, IND.—The Ross Power Equipment Company, Merchants' Bank Building, Indianapolis, it is reported, would like to receive prices (dealers') on a 250-kva., 240/440-volt, 60-cycle, three-phase engine type generating unit, for 125-150 lb. steam, 3 to 5 lb. back pressure; also one 400-kva. generating unit, same as above; one 150-kw., 250-volt compound generating unit, directly connected; one 250-kw. and one 500-kw., either simple or tandem, compound engine.

CHICAGO, ILL.—The plans are being prepared by the International Harvester Company, South Michigan Avenue, for the construction of a series of foundry buildings on Rockwell Street, to cost about \$500,000.

GILLESPIE, ILL.—The Illinois Traction System has secured contract to supply electricity to operate the machinery in the new coal mine being developed in Gillespie. The company will also transport coal mined from the new shaft.

SPRINGFIELD, ILL.—The Springfield Light, Heat & Power Company has applied to the State Utility Commission for permission to issue \$100,000 in bonds, the proceeds to be used for extension to mains and service and the purchase of boilers and mechanical equipment.

TUSCALOOSA, ILL.—The board of education is considering the construction of a heating plant in connection with the high school building.

BRODHEAD, WIS.—Bids will be received by the Electric Light and Water Commission, Brodhead, until April 30, for improvements to the municipal hydroelectric plant, including the installation of a new water power unit, with all appurtenances, to cost about \$35,000.

FAIRWATER, WIS.—The Joint District No. 1, Metomen, Fond du Lac County, has voted to build a new high school, with a manual training department, the cost not to exceed \$3,000, in the village of Fairwater. B. E. Mohner of Fond du Lac is architect.

MILWAUKEE, WIS.—The Austed Leather Company, 560 Commerce Street, is contemplating the installation of an additional steam-driven electric generating unit of 150 capacity and 16 electric motors aggregating 165 hp. The cost is estimated at \$10,000.

MILWAUKEE, WIS.—Plans have been completed by the Milwaukee Paper Box Company, 400 Florida Street, for the construction of a manufacturing plant, 120 ft. by 145 ft. The cost, including machinery, motor and other equipment, is estimated at \$200,000. William C. Carlson is president and treasurer. Schenectzky & Son, 712 Germania Building, architects, are taking bids for the above works.

OREGON, WIS.—Bids are being asked by C. A. Hagan, village clerk, for a 175-gal. centrifugal pump and an auxiliary suction pump with a 220-volt motor, starter, etc.

IVANHOE, MINN.—Bids will be received by Karl A. Hansen, county auditor, court house, Ivanhoe, until May 6, for the construction of the Lincoln County court house at Ivanhoe, separate bids to be submitted on general construction, heating and ventilation, plumbing and electric work. Plans and specifications may be obtained at the above office or at the office of James A. Burner Company, architects, 554 McKnight Building, Minneapolis, Minn.

STILLWATER, MINN.—The Northern States Power Company (Stillwater division) is erecting an electric transmission line to furnish electricity to the plant of the Twin City Forge & Foundry Company in Stillwater. The Twin City company is building docks at its plant here.

HUMBOLDT, IOWA.—Bids will be received by the board of directors of the Independent School District of Humboldt until May 3 for construction of high and grade school building. Separate bids to be submitted on general construction, heating and ventilating, plumbing electrical work, seating and equipment. Plans may be obtained at the office of G. L. Lockhart, Endicott Building, St. Paul, Minn., and Youngerman Building, Des Moines, Iowa, upon deposit of \$5.

RED OAK, IOWA.—The Red Oak Electric Company has applied to the Board of County Supervisors for a franchise to erect and operate electric transmission lines on certain roads in Pleasant Township for a period of 20 years.

KANSAS CITY, MO.—The Kansas City Railways Company, it is reported, has purchased 20 underfeed stokers, two boiler feed pumps, one locomotive crane and one feed water heater.

KANSAS CITY, MO.—The Kewanee Boiler Company, 1420 McGee Street, is contemplating the purchase of a hand-power or electrically-operated traveling crane on track similar to locomotive type with a capacity of 20,000 lb.

ST. LOUIS, MO.—Three warehouse units will be erected by the United States War Department, Second and Arsenal Streets, instead of one as originally planned. The buildings will be 600 ft. by 100 ft., six stories high, and will cost about \$1,200,000. Further information may be obtained from Major James R. Fordyce of the St. Louis quartermaster's department.

BRADLEY, S. D.—The Dakota Northern Power Company is contemplating the erection of a new power plant and the installation of a 300-kw. reciprocating unit, the equipment to be purchased within 30 days. E. H. Lewis is secretary.

VERMILION, S. D.—The proposal to issue \$20,000 in bonds for the construction of a city building, in which to house the equipment of the municipal lighting plant, provide offices for the city officials and quarters for the volunteer fire department, will soon be submitted to the voters.

CARROLL, NEB.—At an election held recently the proposal to issue \$9,500 in bonds for the installation of an electric-lighting system in Carroll was carried.

FIRTH, NEB.—Bids, it is understood, are being asked for extensions to the electric-lighting system. For further information address J. S. Kallemyr.

HEARTWELL, NEB.—Bonds to the amount of \$2,700 have been voted for the installation of an electric-lighting system in Heartwell.

EDGERTON, KAN.—The installation of an electric-lighting system in Edgerton is reported under consideration. Energy to operate the proposed system may be se-

cured from the Wellsville-Gardner electric transmission line.

LEONARDVILLE, KAN.—The Riverside Light & Power Company of Abilene is contemplating extending its service to Leonardville. A street-lighting system, consisting of 20 lamps, will be installed, which will probably be followed by ornamental lamps.

PERU, KAN.—The installation of an electric-lighting system in Peru is reported to be under consideration.

WICHITA, KAN.—The construction of an electric interurban railway from Wichita to Arkansas City, via DeWey, Mulvane, Belleplaine and Winfield, is under consideration. John Madden and W. J. Funk are reported interested in the project.

WINCHESTER, KAN.—The Automatic Electric Light Company is contemplating the construction of an electric-light and power plant near Winchester.

Southern States

CHAPEL HILL, N. C.—Bids will be received by Edward K. Graham, president of the University of North Carolina, until May 7, for the construction of the Physics-Engineering Building. Plans and specifications may be obtained at the office of Charles C. Hook, architect, Charlotte, upon deposit of \$15.

GREENSBORO, N. C.—Contract has been awarded to J. T. Salmon of Durham for the erection of the east wing of the McIver Building for academic building, 65 ft. by 110 ft., at \$68,546; steam heat from central plant, \$8,000; conduit lighting system, \$1,450; also for construction of dormitory, 49 ft. by 158 ft., at \$84,500; steam heat from central plant, \$13,000; conduit lighting system (exclusive of fixtures), \$2,200. Harry Barton of Greensboro is architect. For further information address Dr. J. I. Foust, president of the college.

ROCK HILL, S. C.—Plans have been prepared by Edwards & Sayward of Atlanta, Ga., for the construction of a students' social and activity building and a dormitory, to cost \$125,000 and \$100,000 respectively. Bids will be asked for construction of buildings in from 60 to 90 days.

ATLANTA, GA.—The election which was to have been held on March 25 has been postponed by the City Council until May 26, when the proposal to issue the following bonds will be submitted to the voters: For electric generating plant, \$75,000; water-works pumping station, \$300,000; cyclorama building, \$100,000, and fire department, \$175,000.

REIDSVILLE, GA.—The proposal to issue \$10,000 for the installation of an electric-lighting system in Reidsville is under consideration.

SAVANNAH, GA.—The Chatham County Traction Company has recently been granted a charter to build an electric railway from a connection with the street railway system of the Savannah Electric Company in Savannah to Port Wentworth. The company is capitalized at \$150,000. H. C. Foss, manager of the Savannah Electric Company, is interested in the company.

JACKSONVILLE, FLA.—Plans are being prepared to establish a plant in the Jacksonville ship-outfitting yard of the California Brick Company to install machinery in ship hulls. The plans provide for the erection of machine, blacksmith, coppersmith, paint and electrical shop, garage, storerooms, 11-room office, etc., to cost about \$50,000, also installation of 50-ton and 10-ton traveling cranes. Machinery for the proposed plant, it is understood, has been purchased. The work will be done by the company's own force. It has a contract to furnish and install mechanical equipment in twenty 3500-ton wooden vessels of the Emergency Fleet Corporation owned by the United States government. John Clarence Temple of Jacksonville is general manager.

ST. PETERSBURG, FLA.—The St. Petersburg Lighting Company is contemplating extensions to its power plant, including the installation of a 300-hp. incense water tube boiler and turbine-driven feed pump. This equipment, it is understood, has been purchased.

ENSLEY, ALA.—The Southern Bell Telephone Company is contemplating building an addition to its telephone exchange on Nineteenth Street, between F and G Streets, to cost about \$17,500.

HUNTSVILLE, ALA.—Plans are being considered by Miller Brothers for the reconstruction of its cotton gin, recently destroyed by fire. The gin will be operated by electricity.

LITTLE ROCK, ARK.—The Mutual Power Company is contemplating the installation of a complete shop, new equipment including a lathe with 8-in. to 12-in. boring, 20-in. back-gear drill press, electrical equipment, air compressor, portable engine, small tools, etc.

RECTOR, ARK.—Plans are being prepared by Luther King for the construction of a new power house to operate a new gin house and cotton house now being built.

NEW ORLEANS, LA.—The construction of an electric railway between New Orleans and Mobile, Ala., is reported under consideration.

NEW ORLEANS, LA.—Preparations are being made to establish a vocational school shipbuilding, repairing, etc., in New Orleans, involving an expenditure of from \$2,000 to \$317,000 for buildings and equipment, which will include the construction of four buildings, consisting of administration and auditorium with 6000 sq. ft. provision will be made for training in foundry and machine work, electrical construction, carpentry, etc. J. A. Pratt, president.

NOTES, OKLA.—The City Council is planning to rebuild the municipal electric plant recently destroyed by fire.

SAVANNA, OKLA.—The Savanna Light & Milling Company, recently incorporated with a capital stock of \$2,000, it is reported, is contemplating the installation of a lighting plant in Savanna.

STONEWALL, OKLA.—The Oklahoma Power & Transmission Company is contemplating extending its electric transmission lines to Stonewall to supply electrical power here.

BEAUMONT, TEX.—Bids will be received by J. G. Sutton, city secretary, until May 7 (extension of date) for general construction, heating, plumbing and wiring additions to Ogden Fletcher and Magalia schools. The total cost is estimated at \$100,000. Plans and specifications are on file at the office of Sanguinet, Staats & Little, architects, at Fort Worth and Houston.

CARTHAGE, TEX.—Plans are being prepared by F. T. Rembert and K. S. Melton Longview for the installation of an electric-light plant and ice factory in connection with the Carthage Cotton Oil Company's plant.

CLYDE, TEX.—The installation of an electric-light and power plant in Clyde is under consideration. Robert Cook is reported interested in the project.

NIXON, TEX.—The Nixon Electric Light & Power Company, recently incorporated with a capital stock of \$12,000, is contemplating the construction of an electric-light and power plant in Nixon.

RIO GRANDE, TEX.—The capital stock of the Rio Grande Ice, Water & Light Company has been increased from \$24,000 to \$30,000.

ROUND ROCK, TEX.—Preparations are being made by S. E. Bergstrom of Kerens for the installation of an electric-light plant in Round Rock. Machinery, it is understood, has been purchased.

Pacific and Mountain States

COLVILLE, WASH.—The Stevens County Power & Light Company of Colville has petitioned the Commissioners of Stevens County for a franchise to erect an electric transmission line over the public roads in Stevens County.

SEATTLE, WASH.—The Puget Sound Traction, Light & Power Company is contemplating improvements to its power house at 6600 Fourteenth Avenue South, including the installation of a coal conveyor, concrete tunnels and hopper.

TACOMA, WASH.—At an election held April 16 the proposal to issue \$4,000,000 in bonds for the construction of the proposed additional power plant was defeated.

COLUSA, CAL.—The Colusa Land & Water Company, it is reported, is contemplating the development of electricity for agricultural purposes. The proposed work will include a main canal, 8.7 miles long, a pumping plant, equipped with one 42-in. pump having a capacity of 100 sec.-ft., driven by a 400-hp. motor, and two 26-in. pumps with a capacity of 50 sec.-ft. each, driven by a 200-hp. motor. The cost of the project is estimated at \$219,890.

LOS ANGELES, CAL.—A resolution has been introduced in the City Council providing for the use of electricity from the municipal electric plant for the new Broadway lighting system.

LOS ANGELES, CAL.—The Pacific Electric Railway Company has been instructed by the Board of Public Utilities to double-track its car line between Wilmington and Long Beach immediately.

LOS ANGELES, CAL.—The Public Service Commission has awarded the contract for laying of the submarine cable across the channel in the harbor to serve the substation to be erected at Fish Harbor, which will furnish electrical service to the proposed plant of the Southwestern Shipbuilding Company.

LOS ANGELES, CAL.—Plans are being considered by the power bureau for the installation of two submarine cables across the main harbor channel from the foot of Fifth Street in the San Pedro district to serve the city power substation, to be erected near Fish Harbor, which is to furnish energy to the shipbuilding plant.

MONTEREY, CAL.—The City Council has authorized the city engineer to prepare plans for extending the electrolier street-lighting system on Main Street from Scott Street north toward Decatur Street.

ONTARIO, CAL.—The San Antonio Water Company of Ontario is contemplating the construction of a new electric power house in San Antonio Canyon. Glenn D. Smith is manager.

RICHMOND, CAL.—The City Council has voted \$12,000 for electrical equipment for the municipal wharf, now under construction. Contracts have been awarded for two electric trucks, at a cost of \$4,383, to the United Vehicle company and for a 5-ton electric crane to the Cyclops Iron Company, at \$7,500.

ROUND MOUNTAIN, CAL.—The development of a hydroelectric power plant at a

drop near Round Mountain is reported to be under consideration by Wilbur O. Lusk of Los Angeles. The plans provide for the construction of a ditch and pipe line, 6.2 miles long. It is estimated that 7500 kw. can be developed.

SAN FRANCISCO, CAL.—The contract for electrical work in connection with the yard work at the southeast wing of the San Francisco Hospital has been awarded to J. Burtchall, 357 Ellis Street, at \$4,975.

PUEBLO, COL.—The Arkansas Valley Railway, Light & Power Company has recently completed an extension of its transmission lines to the Outland Ranch, and has accepted a contract to extend its lines to other ranches in that vicinity.

Canada

NEW WESTMINSTER, B. C.—The Campbell River Lumber Company has recently installed a step-down transformer station to convert the high-tension current of 12,000 to 2200 volts. The amount of energy used in the mill is about 950 hp.

HAMILTON, ONT.—Plans are being prepared by the Stone & Webster Engineering Corporation, 147 Milk Street, Boston, Mass., for the construction of a new plant at Old River at its junction with the Baltimore & Ohio Railroad for the Hamilton & Rossville Hydraulic Company on land which has been given the company in exchange for its present quarters. The company has been obliged to change its location owing to the flood prevention work by the Miami Conservancy District. The plans provide for the installation of three generating units of 800 kw. each.

SUDBURY, ONT.—Bids will soon be asked by W. J. Ross, clerk, for one electrically-driven pump of 12,000 gal. capacity, and one 175-lb., two-phase, 220-volt alternating-current induction motor.

MONTREAL, QUE.—The Ferro Alloy Company, it is reported, is planning to build a plant on the St. Maurice River in the Province of Quebec to secure the advantages of the cheap water power there.

SHAWINIGAN FALLS, QUE.—Plans are under consideration, it is reported, for the installation of three additional units of 20,000 hp. each in plant of the Laurentide Power Company, increasing the output to 180,000 hp. J. E. Aldred, 24 Exchange Place, New York, N. Y., is president of the company.

Miscellaneous

HAVANA, CUBA.—Contracts have been placed by the Havana Electric Railway, Light & Power Company for equipment for railway substations, consisting of two 2000-kw. rotary converters, six-phase, 60 cycles, 450 r.p.m.; six 750-kva., single-phase, oil-insulated, self-cooled transformers, 13,200 volts to rotary voltage; also switch and control equipment, to the Westinghouse Electric & Manufacturing Company.

(Issued April 9, 1918.)

261,771. MOTOR-CONTROLLED BRAKE; John S. Coldwell, Milwaukee, Wis. App. filed March 19, 1917. Improvements.

261,772. SYSTEM FOR SIGNALS AND MOTOR CONTROL FOR ELECTRIC ROADS; Roy V. Collins, New York, N. Y. App. filed May 13, 1913. Improvements.

261,777. OVERLOAD SWITCH; James K. Delano, Jr., Louisville, Ky. App. filed March 8, 1915. For use on low-voltage work.

261,790. CIRCUIT - CONNECTOR SWITCH; Harry A. Douglas, Bronson, Mich. App. filed Aug. 23, 1917. Improvements.

261,817. ELECTRICAL SYSTEM AND APPARATUS THEREFOR; John W. Jepson, New York, N. Y. App. filed Oct. 2, 1908. For voltage regulation.

261,856. SUPPORTING MECHANISM; Thomas B. Rule, Arklow, Ireland. App. filed Aug. 17, 1916. Supports an electric lamp.

261,870. ELECTRIC TRANSMITTING SYSTEM; Olof A. A. Tenow and Erik G. Ahnstrom, Stockholm, Sweden. App. filed Dec. 29, 1916. Remote control.

261,874. ELECTRIC FITTING; Samuel B. Van Ranst, Syracuse, N. Y. App. filed Feb. 11, 1910. Conduit fitting for use as a receptacle for snap switch.

261,884. IGNITION APPARATUS FOR INTERNAL-COMBUSTION ENGINES; Lionel M. Wolffsohn, Hoboken, N. J. App. filed March 18, 1916. Improvements.

Record of Electrical Patents

Notes on United States Patents

1,261,891. ARC-LIGHT CARBON; Hertha Ayrton, Hyde Park, London, England. App. filed Sept. 28, 1914. Improvements.

1,261,906. ELECTROMAGNETIC REGULATOR; John A. Coleman, Cleveland, Ohio. App. filed April 8, 1916. For operating valves and dampers.

1,261,928. ELECTRIC-LAMP INSTALLATION; Monroe Guett, Hartford, Conn. App. filed April 5, 1917. Lamp socket connected into the electrical circuit is inaccessible for the purpose of the insertion or removal of a lamp.

1,261,943. PLATE-WELDING PROCESS AND ARTICLE; Walter B. Lasher, Bridgeport, Conn. App. filed May 31, 1917. Welds thin plates.

1,261,968. MAIL - DISTRIBUTING SYSTEM; Simon B. Storer, Syracuse, N. Y. App. filed Dec. 11, 1914. Improvements.

1,261,971. ELECTRIC RIVETING MACHINE; Albert C. Taylor, Warren, Ohio. App. filed Sept. 19, 1916. Improvements.

1,261,975. HALL-BUTTON CUT-OUT SWITCH; Clarence W. Wheeler, Chicago, Ill. App. filed May 21, 1915. For automatic electric elevators.

1,261,999. DYNAMO-ELECTRIC MACHINE; Ernest J. Andrews, Chicago, Ill. App. filed June 11, 1912. For starting internal-combustion engines.

1,262,000. BATTERY METER; William Anthony, Clyde, Ohio. App. filed June 4, 1917. For measuring the energy or electromotive force of batteries.

1,262,019. VOLTAIC CELL; Miller E. Conrad, Atlantic, Iowa. App. filed Feb. 7, 1917. Improved depolarizing cell.

1,262,020. VOLTAIC CELL; Miller E. Conrad, Atlantic, Iowa. App. filed Feb. 7, 1917. Improved depolarizing cell.

1,262,037. TROLLEY RETRIEVER; Charles E. Gierding, Mansfield, Ohio. App. filed March 19, 1911. Improvements.

1,262,045. ELECTROLYTIC ALUMINUM; J. J. B. Herrshoff, Jr., Richmond Hill, N. Y. App. filed Dec. 4, 1915. For use in refining.

1,262,072. ELECTRICAL APPARATUS FOR HEATING STILL, BOILERS AND THE LIKE;

Charles O. Lorenz, Fort Arthur, Tex. App. filed May 8, 1917. Heating element not affected by repeated changes in temperature.

1,262,080. ELECTRIC STARTER; Albert H. Midgley, Acton Vale, England. App. filed July 10, 1915. For internal-combustion engines.

1,262,088. SPARK-PLUG TESTER; Alonson D. Perkins, New York, N. Y. App. filed May 10, 1916. For determining if the electric circuit of a spark plug has been accidentally broken without requiring the plug to be removed from the engine.

1,262,237—Incandescent-Lamp-Bulb Socket

1,262,103. APPARATUS FOR TESTING CABLES; Edmund O. Schweitzer, Chicago, Ill. App. filed Feb. 1, 1912. For fault or ground.

1,262,112. TELEPHONE SYSTEM; Frank M. Slough, Elyria, Ohio. App. filed May 15, 1915. Improvements.

1,262,113. TELEPHONE SYSTEM; Frank M. Slough, Elyria, Ohio. App. filed July 26, 1915. Improvements.

1,262,128. TROLLEY RETRIEVER; William C. Starkey, Mansfield, Ohio. App. filed Nov. 21, 1914. Improvements.

1,262,141. ELECTRIC INCANDESCENT LAMP; Edward Terry, Brixton, London, England. App. filed Oct. 2, 1915. Filament renewable.

1,262,148. ELECTRIC TOOL; Alex Wendelburg, New York, N. Y. App. filed Sept. 4, 1913. Operating means for the tool-driving motor.

1,262,149. CONTROLLER FOR ELECTRIC HAMMERS; Alex Wendelburg, New York, N. Y. App. filed Aug. 26, 1914. Means for delivering current to the operating coils of the hammer at predetermined time intervals.

1,262,150. METHOD OF AND APPARATUS FOR CONTROLLING A CIRCUIT; Paul R. Werner, Philadelphia, Pa. App. filed Oct. 13, 1915. Saturated magnetic field is fully developed before the movement of the armature takes place.

1,262,155. TERMINAL CONNECTOR FOR ELECTRICAL CONDUCTORS; Otto Zimmerman, New York, N. Y. App. filed July 15, 1916. Double-eyelet type for flexible electric conductors.

1,262,173. APPARATUS FOR NEUTRALIZING STATIC ELECTRICITY; William H. Chapman, Portland, Me. App. filed April 21, 1917. Removal of static electricity from paper, fabrics and other material in process of manufacture.

1,262,187. CONTROLLING SWITCH FOR SYNCHRONOUS MOTORS, ROTARY CONVERTERS AND SYNCHRONOUS RECTIFIERS; James K. Elderkin, Jr. App. filed July 30, 1914. Starts motors so as always to synchronize with the fields excited at the same polarity.

1,262,198. MAGNETO-GENERATOR; Edward B. Jacobson, Springfield, Mass. App. filed March 13, 1915. Operating parts effectively housed from dust and dirt.

1,262,228. STORAGE - BATTERY SEPARATOR; William Morrison, Chicago, Ill. App. filed Feb. 20, 1918. Sheet of wood impregnated with barium sulphate.

1,262,233. ELECTROMAGNETICALLY OPERATED DEVICE; Ethelbert T. R. Murray, Radlett, and George F. Shutter, Streatham, London, England. App. filed March 23, 1916. Relay in which the current necessary to

operate the device can be varied by changing the length of the air gap.

1,262,234. CIRCUIT BREAKER; Ethelbert T. R. Murray, Radlett, and George Frederick Shutter, Streatham, London, England. App. filed March 21, 1916. Improvements.

1,262,237. INCANDESCENT - LAMP - BULB SOCKET; Charles A. Nelson, Chicago, Ill. App. filed May 22, 1914. The use of blocks or masses of porcelain, hard rubber, etc., is eliminated.

1,262,248. APPARATUS FOR THE ELECTROLYTIC PRODUCTION OF COPPER AND OTHER METALS; Marcel Pelter-Lloyd, Boulogne-sur-Seine, France. Improvements.

1,262,257. MOTOR CONTROLLER; Harrison P. Reed and Walter C. Kennedy, Milwaukee, Wis. App. filed March 1, 1915. Field-controlling means for motors having shunt-field windings.

1,262,264. ELECTRODYNAMIC MACHINE; Amato N. Sammarone, Akron, Ohio. App. filed Aug. 16, 1916. Improvement in the commutator support.

1,262,266. MOTOR MECHANISM FOR VIOLIN PLAYERS; Henry K. Sandell, Chicago, Ill. App. filed Dec. 19, 1914. Improvements.

1,262,270. POCKET LAMP FOR FIREARMS; Paul Schmidt and Carl Dobslaw, Berlin, Germany. App. filed April 23, 1914. Improvements.

1,262,276. MOLD; Walter E. Skidmore, East Liverpool, Ohio. App. filed Aug. 8, 1917. Molded product is automatically released without breaking.

1,262,290. REGULATOR FOR ELECTRIC MOTORS; George H. Whittingham and William T. Holmes, Baltimore, Md. App. filed May 1, 1917. Electric motors used for driving individual machines.

1,262,307. PORTABLE ELECTRIC FUSE LIGHTER; Albert S. Cole, Livermore, Cal. App. filed May 23, 1916. Improvements.

1,262,315. TELEPHONE-EXCHANGE SYSTEM; Bert G. Dunham, Hawthorne, N. J. App. filed Oct. 5, 1915. For telephone-exchange systems utilizing automatic switches.

1,262,320. PORCELAIN PULL SOCKET; Edgar H. Freeman, Trenton, N. J. App. filed Nov. 8, 1915. No exterior metal parts.

1,262,323. TELEPHONE-EXCHANGE SYSTEM; Charles L. Goodrum, New York, N. Y. App. filed Oct. 29, 1917. Automatic line finders.

1,262,326. AUTOMATIC INTERRUPTER FOR ELECTROMAGNETICALLY OPERATED PAWL-AND-RATCHET MECHANISM; Georg Grabe, Berlin, Germany. App. filed Feb. 15, 1916. Improvements.

1,262,330. ELECTRIC SWITCH; Monroe Guett, Hartford, Conn. App. filed Nov. 21, 1913. Improvements.

1,262,331. ELECTRIC SNAP SWITCH; Monroe Guett, Hartford, Conn. App. filed Nov. 20, 1916. Improvements.

1,262,333. INDICATING DEVICE; John A. Hall, East Orange, N. J. App. filed Oct. 20, 1916. For use in telephone systems.

1,262,352. CALLING DEVICE; William Kaising, Chicago, Ill. App. filed Nov. 19, 1915. Used in telephone substations for controlling automatic switches.

1,262,359. IMPULSE-TRANSMITTING DEVICE; John A. Kropp, Oak Park, Ill. App. filed Oct. 11, 1916. Relates to senders employed in automatic and semi-automatic telephone exchanges.

1,262,360. SIGN; Frank O. Ladwig, Chicago, Ill. App. filed Feb. 10, 1917. Motor-operated changeable sign.

1,262,365. AUTOMOBILE SIGNAL; James P. McDermott, New Haven, Conn. App. filed May 4, 1917. Improvement.

1,262,378. LOCKING DEVICE FOR COIL BOXES AND SWITCHES; Harry W. Neal, Indianapolis, Ind. App. filed Dec. 21, 1916. To control the electric circuits in automobiles.

1,262,382. MAIL BOX; Roy J. Oliver, Prescott, Ariz. App. filed Nov. 29, 1916. Signal given when mail has been deposited within the box.

1,262,391. ELECTRIC RAIN ALARM; George A. Sabol, Clairton, Pa. App. filed Aug. 10, 1917. Improvements.

1,262,396. ARC WELDING; John A. Seede, Niskayuna, N. Y. App. filed Jan. 9, 1914. Limits the current supplied to the work to a low value at striking.

1,262,411. CAR-LIGHTING SYSTEM; John F. Trittle, Schenectady, N. Y. App. filed Dec. 18, 1913. Improvements.

1,262,424. ELECTRICAL SWITCH; Albert C. Wynne, Birmingham, England. App. filed April 17, 1916. Key-operated oscillating-arm switch.

1,262,435. ELECTRICALLY CONTROLLED LOCK; Gordon G. Berg, Chicago, Ill. App. filed

April 6, 1916. Door lock may be positively latched to prevent its manual operation.

1,262,453. PROCESS FOR VOLATILIZING ORES; Selden I. Clawson, Salt Lake City, Utah. App. filed Aug. 11, 1909. Apparatus in which the chlorine gas may be reclaimed from the volatile chlorides and reused in the volatilization of the ores.

1,262,463. FUSE PLUG; C. L. Dickson, Chattanooga, Tenn. App. filed July 8, 1916. Fuse-lock attachment which is to prevent the theft of energy.

1,262,487. MECHANICAL LOCKING DEVICE FOR PRESS CONTROLLERS; George W. Harrold, Philadelphia, Pa. App. filed Jan. 27, 1916. Improvements.

1,262,490. METHOD OF APPARATUS FOR TRANSLATING ELECTRICAL VARIATIONS; Peter Cooper Hewitt, Ringwood Manor, N. J. App. filed March 30, 1907. Flow of electric current through a gas or vapor utilization.

1,262,491. METHOD OF AND APPARATUS FOR TRANSLATING ELECTRICAL VARIATIONS; Peter Cooper Hewitt, Ringwood Manor, N. J. App. filed March 30, 1907. Improvements.

1,262,492. APPARATUS FOR AND METHOD OF TRANSLATING ELECTRICAL VARIATIONS; Peter Cooper Hewitt, Ringwood Manor, N. J. App. filed March 30, 1907. Electrodes used in operative relation to a gas or vapor-carrying current.

1,262,496. TELEPHONE-EXCHANGE SYSTEM; Edward E. Hinrichsen, East Orange, N. J. App. filed Aug. 2, 1916. Improvements.

1,262,497. ELECTRICAL SYSTEM OF SHIP PROPULSION; Henry M. Hobart, Schenectady, N. Y. App. filed Sept. 1, 1915. Improvements.

1,262,531. IGNITION SYSTEM FOR EXPLOSION ENGINES; Henry A. Lyon, Solomon, Kan. App. filed Aug. 22, 1916. Improvements.

1,262,534. IGNITION MECHANISM FOR INTERNAL-COMBUSTION ENGINES; Samuel C. McKeown, Newark, N. J. App. filed June 21, 1916. Improvements.

1,262,544. IGNITION DEVICE; William B. Moses, Brookline, Mass. App. filed March 10, 1916. Improvements.

1,262,558. ELECTRICAL MEASURING INSTRUMENT; Willard E. Porter, Lynn, Mass. App. filed March 18, 1915. Improved adjusting means for the control spring.

1,262,581. BATTERY CONSTRUCTION; William Gardiner, Chicago, Ill. App. filed Feb. 7, 1916. Improved separator.

1,262,582. PROTECTIVE DEVICE; John F. Graybill, York, Pa. App. filed Oct. 5, 1914. For secondary circuits of electric distribution system.

1,262,585. ELECTRIC MOTOR; Edgar L. Hollingshead, Minneapolis, Minn. App. filed

1,262,585—Electric Motor

March 30, 1916. Rotor is free from winding, insulated bars or electrical fittings of any kind.

1,262,587. DYNAMO - ELECTRIC MACHINE; John W. Jepson, Depew, N. Y. App. filed May 8, 1913. For charging storage batteries and supplying lights on motor vehicles driven by gas engines.

1,262,599. ELECTRIC MOTOR; Thomas J. Murphy, Rochester, N. Y. App. filed Oct. 29, 1915. Used to produce a steady arc light of high candlepower for moving pictures.

Number 18

America's Belated Recognition of Oliver Heaviside

WE PUBLISH in another column an announcement that the board of directors of the American Institute of Electrical Engineers has elected Oliver Heaviside an honorary member. Thus another great name is added to the small list of honorary members of the Institute, which comprises André Blondel, S. Z. de Ferranti, C. E. L. Brown and Guglielmo Marconi. It is, indeed, a belated tribute which America thus pays to the powerful English mathematical physicist, whose brilliant work on electromagnetic theory laid the foundation upon which the great superstructure of long-distance telephony has since been reared. When this generation bears in mind that as early as 1887 Oliver Heaviside demonstrated theoretically, and then urged practically, the advantage of inductance in telephone circuits; when it has further considered that the British Post Office Department, then under Sir William Preece, failed completely to understand his theories, so much so that Sir William Preece suggested for a transatlantic telephone cable a cable in which the electrostatic capacity was increased, it is little wonder that it has taken some time to bring about a clear recognition of Heaviside's fundamental principles underlying the propagation of electric impulses along wires and cables.

Unceasingly, in the teeth of a gale of "scienticulist" ignorance and prejudice, this great mathematician developed his theories and urged experimental work along the lines laid down by him, aiming at an increase of the inductance per unit length of the cable or conductor. In a series of brilliant articles published in 1893 in the London *Electrician* he suggested having "large distributed inductance together with inductance in isolated lumps. This means the insertion of inductance coils at intervals in the main circuit. . . . The electrical difficulty here is that inductance coils have resistance as well, and if this be too great, the remedy is worse than the disease. . . . This means using coils of low resistance and the largest possible time constants."

Twenty-five years have passed. Under the direction of Col. J. J. Carty, telephone engineers of this country have demonstrated the truth and the applicability of Oliver Heaviside's scientific reasoning. Great is truth, though it may be slow in prevailing!

Not alone, however great this work has been, can it be viewed as Heaviside's life work. Besides numerous contributions to the science of mathematics of utmost and revolutionary importance, there are the Heaviside units, called the "rational" units; there is the "rational" current element used throughout his work by Sir

Joseph John Thomson; there are the fundamental equations of the motion of an electrically charged body, with all the ramifications of mathematical and scientific work, which has culminated in the theory of the electron, and inseparably connected with Heaviside's name is the "distortionless circuit" and its beautiful theory. A busy age may plead preoccupation in extenuation of its failure to give earlier official recognition. So many are the subjects touched upon in Heaviside's writings, so absorbing and stimulative are these contributions to electrical science, that they have been an inexhaustible source from which lesser men have drawn material for interesting and instructive papers. The theory of the distortionless circuit, the building up of the steady state from a conception of direct and reflected waves, the use of operators—all these are but a few of the contributions made more than a quarter of a century ago, and they are cited at random from the wealth of Heaviside's papers. May this recognition of one of the greatest mathematical physicists the world has ever known convey to Great Britain and her men of science another message from America that in realization of each other's strength must lie the basis of their enduring greatness and invincibility.

Protect the Credit of the Utilities

IT WAS not necessary under normal conditions to give serious concern to the subject of credit of well-managed electric utilities. They had good credit. It is highly necessary to give most careful attention to this vital question under the war conditions of to-day. Herbert A. Wagner, in the suggestive article published in this issue, discusses critically the vital problem of maintenance of sound credit. It cannot safely be ignored or left to haphazard decision. This is a matter which is intimately connected with the operation of war industries at war-time speed and with satisfactory service to the general public. It is not the part of wisdom to let these properties be subject to the economic burdens of war and at the same time to withhold relief from them through larger revenue where higher rates are required.

Recognizing that the paramount obligation of the utility is to the public which it serves, Mr. Wagner discusses various other considerations which should be kept in mind. These are, first, the positive obligation to bondholders, who may throw the property into confusion, endangering the equity of shareholders, if their interest is not met; second, the obligation to shareholders, which is only slightly less than the obliga-

tion to bondholders, for the public utility stock certificate with state rigid regulation represents investment and limited return, not speculation and a fair chance of big profits; and, third, most important of all to the large body of consumers, the urgent importance of meeting the need for ever-increasing service in a growing community. To comply with the demand for service, which is a very real and crying demand in these times, you have to provide plant. To buy plant takes money. And one cannot get investment money at low rates from the bankers unless credit is good, unless earnings show ability to pay, unless the record of the past is unequivocal payment of obligations and sustained earning power.

Only the keen appreciation of the crisis which lies just on the border line of sustained credit or damaged credit justifies the utilities in bringing their problems to public attention when the nation is at war. Ordinary trials they would face without complaint. But they cannot afford now to lose the ability to cope uncrippled with whatever the future holds. They cannot dissipate strength in struggle when it is imperatively needed for efficient operation. They can weather a storm if clear, smooth seas lie ahead. It is plainly the hour when the utilities have the right to insist that all of the obligation is not resting upon them. Some of it belongs to the other side. Maintained credit will keep them in the best condition to give the service which will help to win the war. The utilities ask in confidence that their business be set and kept on a self-sustaining basis, so that irrespective of government aid in financing they may make a good showing and have a reasonable surplus.

Seriousness of the Coal Situation

THE only certain feature about the coal situation is its seriousness. This unfortunately does not appear to grow less with time. Indications are that fuel will be as hard to get as ever and with the coal zoning system many utilities will have in addition to content themselves with inferior coal. Prudent managers, therefore, will lay in as large a supply of fuel as they can obtain before railroad service becomes any worse, and operators will adapt their furnaces to the grade of coal allotted them. This is sensible as well as patriotic. So far as public utilities are concerned the Fuel Administration is doing its utmost to provide for their wants, but the best laid plans often go awry owing to circumstances beyond the control of the planner. The Fuel Administration is not the Railroad Administration, and thereon hangs a tale. Just as long as co-operation between administrations and co-ordination of various governmental activities are lacking, to that extent there will be confusion and inefficiency. Coal at the mines is of no service to a utility. It can only be used when in the bunkers of power houses, and to put it there cars are necessary. If the Railroad Administration does not provide the cars, the Fuel Administration is helpless. The zoning system of the Fuel Administration was devised primarily to help the Railroad Administration, but no one-sided co-operation is ever very effective. The railroads, of course, are deluged with freight, and some day there may be a freer movement of low-grade freight, which includes

coal. Until that day arrives, however, the coal situation will continue to be serious. The safest way to provide against freight contingencies is to get all the coal obtainable and store the surplus. In such a plan the co-operation of the Fuel Administration is assured.

Additions to the Commonwealth Edison Plant

NO BETTER evidence of the difficulty of keeping pace with the demand of a great and rapidly growing city can be found than in the description of some of the new work at the Northwest station of the Commonwealth Edison Company which we publish this week. The first plant contained two 20,000-kw. units, to which have now been added three 30,000-kw. turbo-generators and one of 35,000 kw., the last-named for 25-cycle operation like the original plant. When in full operation the station will be able to furnish 85,000 kw. at 25 cycles and 80,000 kw. at 60 cycles. To provide for this immense output corresponding changes have been necessary in the boiler room. Each of the first two machines of 20,000 kw. was fitted with ten boilers per unit. The last generators, in spite of their greatly increased rating, have only five double boilers each.

This change is an impressive demonstration of the tendency toward getting boiler units somewhere nearly commensurate with the generator capacity. Whether the time will ever come when it will be the practice to install one boiler unit per generator is another matter. Probably not, since boilers require overhauling on account of the nature of their service, and it is desirable to have the boiler capacity sufficiently subdivided to permit one section to be taken out of service without too great inconvenience.

The additions to the plant have also involved a general change from steam to electric drive for all the auxiliaries, a change thoroughly in keeping with the general trend of practice for obtaining higher efficiency and greater convenience. All the new units are equipped with direct-connected exciters, and the circuits are so connected that each unit can be fully controlled from its own particular panel. They are all, too, equipped with control relays which are somewhat unusual in the thoroughness of the operations conducted by them. When tripped they act in succession to open the main generator switches, the generator field switch, the generator neutral switch, and the ventilating-fan switch in the case of the machines which have artificial ventilation.

Exploring coils installed in the generators are connected to temperature indicators in the operating gallery, and similar coils in the air intakes of the machines give continuous indications of the temperatures reached in operation. The whole switching equipment of the new plant is installed in the more recent portion of the switch house, which contains a basement for cables, high-tension buses on the first floor, oil and disconnecting switches on the second floor and the oil-switch mechanism on the third floor. Interesting details regarding the arrangement of the switchboard connections and apparatus in the plant are included. Our readers will find in the diagrams a wealth of information regarding the complete equipment of this very modern and highly organized plant.

Taking Proper Care of Reactors

ALTERNATING-CURRENT stations grow bigger and bigger, and the importance of reactors to serve as protection against short circuits becomes greater and greater. In the earlier days of alternating-current service every effort was made to improve generators in the direction of lowered reactance, so as to obtain good inherent regulation to facilitate the keeping up of uniform voltage. The first alternators were extremely unsatisfactory in this respect, but as bigger machines came into use it was found that a moderately high reactance was very desirable to avert trouble from short circuits, particularly where machines were operated in parallel. Later it was found advisable to put this reactance in part at least outside the machine, chiefly for mechanical reasons. The average engineer has a very meager idea of the tremendous forces exerted by reactors when big currents arising from a short circuit occur. The installation of reactors transfers the major part of the troubles from the generator to the reactor, hence in the design and installation of these much care has proved to be necessary.

M. E. Skinner's paper on this subject throws a vivid light on the electrodynamic problems of reactor installation. The reactors in practical use are always without iron cores. They are akin to the primary circuit of a coreless transformer adapted to carry very great currents, and usually take the form of coils of bare wire with the turns supported on fireproof and non-magnetic material. They are too big to immerse conveniently in oil tanks, so reliance is placed on air as a dielectric. The temperatures reached under short-circuit condition may be very high. Ordinary insulating materials would be of little service even if one attempted to employ them.
